Hinkle's Ore Feeder.

Philip Hinkle of this city recently obtained through the MINING AND SCIENTIFIC PRESS Patent Agency a patent on an improved ore feeder, an engraving of which is shown herewith.

The chute or discharge opening at the lower end of the ore-hopper is made preferably of cast-iron, and so secured as to relieve the lower end of the hopper itself from wear, obviating the necessity of replacing the entire hopper, by reason of its lower end wearing out from the friction of the passing ore. The feeding tray is so made that the falling tappet of the stamp mill will cause a backward movement of this feeding tray. It can also be arranged to feed roller-mills.

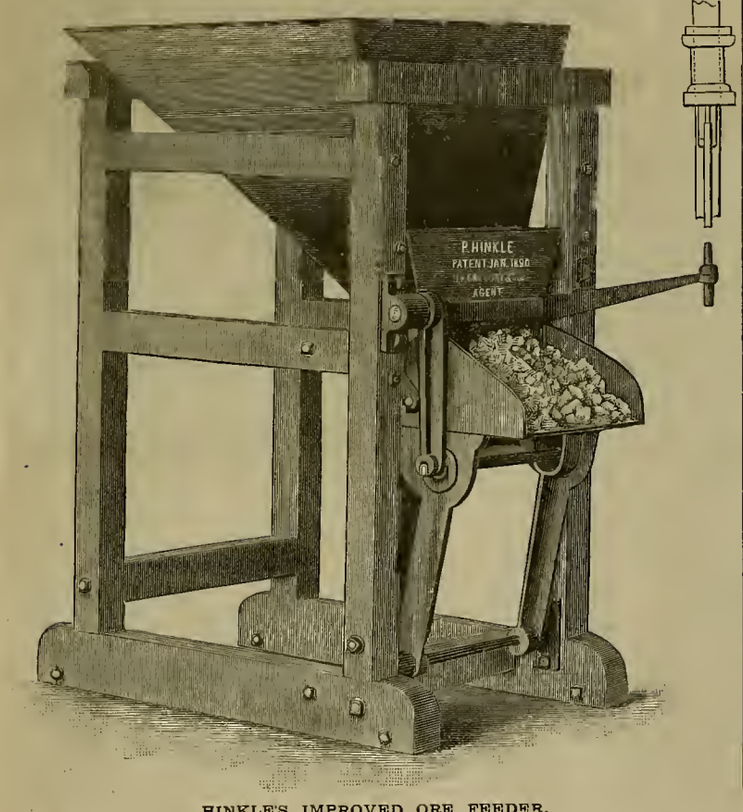
Ore placed in the hopper will fill it and a portion will flow out through the mouth upon the tray, and when, by the swinging or oscillation of the tray it moves forward, another portion of the ore will move out upon the tray. When the tray has again moved backward, a transverse bar prevents the ore moving backward and will force it forward a short distance upon the tray, depending upon the amount of oscillation which is given to the tray, this being subject to regulation at will.

The next forward movement of the tray carries this body of ore forward with it and allows another small portion of the ore to flow out of the hopper; and when the front portion of the ore has reached the front edge of the tray by these successive movements, it will be gradually caused to fall off and drop into the crushing apparatus of whatever description may be employed.

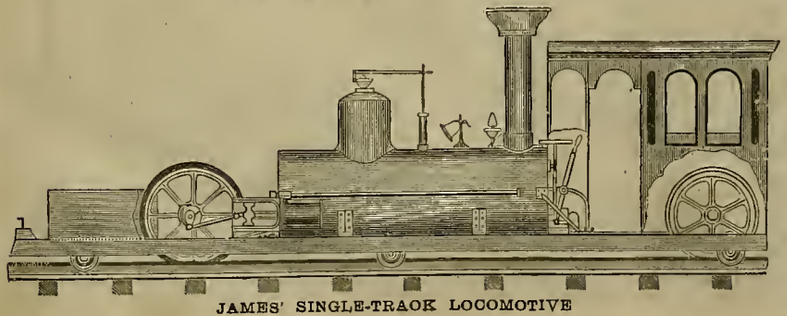
The amount of movement of the tray is regulated by a rod passing through a fixed plate. By screwing certain adjusting nuts on the rod one way or the other, the tray will be drawn back or allowed to fall forward, and thus the amount of motion which is given will be regulated. A removable steel plate is fixed to the tray below the bar to take the wear. When the eccentric is used to actuate the tray, the movement of the latter will be a positive one and dependent upon the throw of the eccentric; but if the tray is to be used on a stamp-mill, as described, the weight of the tray and the ore upon it in front of the fulcrum will cause it to move forward promptly by gravitation as soon as released from the power which draws it back.

The loosely fixed bar which acts as a stop and pusher upon the tray, being made of steel will be subjected to little or no wear, and will always lie closely upon the tray, so as to prevent any escapes of ore to the rear. It can also be readily removed and replaced at any time.

The advantage of the tray supported from below is that moving about a fulcrum-point, which is below the tray, the tray moves in a small convex arc of a circle, which is more conducive to its prompt return after having been forced back, and also produces a better result in feeding. H. P. Gregory & Co. are the Pacific Coast agents for this improved feeder.



HINKLE'S IMPROVED ORE FEEDER.



JAMES' SINGLE-TRACK LOCOMOTIVE

A Single-Track Locomotive.

Last week we gave a brief account of the James engine for traction purposes, which was tested on a small section of track in this city. On this page is a cut of this "single-track locomotive," which was built for Mr. James by Mr. Milchner at H. W. Rice's shop on Bluxome street. It is 24 feet long and six feet wide. The pair of cylinders 8x16 are connected with a drive-wheel 30 inches in diameter. The other wheel is 24 inches in diameter, and both are 30 inches wide, with the flanges in the centers and run upon two pieces of timber for rails 4x12 fastened upon ties two feet between centers and four feet long. The engine is provided with a 25 horse power boiler and reverse gear complete.

The object of this invention is to furnish a cheap system of transportation to localities where the traffic would not pay either a narrow or a broad-gauge railway. Under favorable conditions, it is claimed this railway can be constructed for $1000 per mile. The profits that this system of road would make would all be consumed in paying interest on either a broad or narrow gauge.

CORRESPONDENCE.

We admit, unindorsed, opinions of correspondents.—EDS.

The Mines of El Dorado County.

[From our Traveling Correspondent.]

El Dorado county at this time is an inviting field for the mining operator. The "mother lode" passes through the county, and in its great length affords scope for operations on an extensive scale. The Old Church Union and other mines have proven beyond all doubt that the veins are permanent and high in gold values. At this time the working properties are situated both on and off the mother lode. From Plymouth to Placerville the mines are on a vein running parallel with the mother lode, but situated a mile to the west. By some this vein is considered a fork or feeder of the mother lode. Some geologists contend that the whole mile in width is part of the mother lode, inasmuch as the mother-lode walls are found on the west of this vein. The mother lode proper is not worked at any point on this section.

Near El Dorado and about midway to Shingle Springs is a contact between the serpentine and common slate. This has been prospected at one point by the Greenstone and the ore found to carry tellurides. Accompanying the mother lode to the west is a large porphyry dyke filled with quartz seams carrying heavy gold. From this dyke large amounts have been extracted by hydraulicking off the surface as at Greenwood, and by pocket miners. This porphyry belt runs from 50 to 300 feet in width and crops all the way across the county. At present the most heavily mineralized portion near the walls is being milled at the Shaw mine, and the entire dyke at the Dalmatia at Kelsey. Various estimates have been placed on the milling value of the dyke. Senator George Hearst is reported to have put the entire body at $3 a ton.

Going north from Placerville, the mother lode continues to fork as at El Dorado and at Garden Valley. The porphyry is the foot-wall of one group of mines and the hanging-wall of another parallel group. There does not seem to be any marked difference in the value of the two. In the Grizzly Flat district the mines are in the granite belt, and may be said to correspond to those of Soulsbyville, Tuolumne county, and West Point, Calaveras. Arnle, they are very high in grade. Drifting on old river channels is being pursued with the best results, and this branch has never had as bright an outlook as at the present time. I think it will be found that the mother lode and the accompanying veins increase in their mineral wealth as they go north, and it may be that in gold, as in silver, the altitude will affect the value of the veins.

El Dorado.

The Oakland, formerly known as the McNulty, is now being developed by Supt. R. S. Ran, who was formerly superintendent of the Sutro tunnel. The mine is opened by crosscut tunnel that cuts the vein 150 feet deep. From this point a shaft has been put down 300 feet on the vein which averages 4½ feet in width. The ore milled from this vein in 1875 went from $15 to $20 a ton. The mine has a complete 10-stamp mill. It is Mr. Ran's intention to sink 300 feet deeper on the vein and drift. If then the shoot is of sufficient length, the mill will be enlarged and the property put in first-class shape for extensive and economical working. The mine is on the west branch of the mother lode and two miles south of the Old Church Union.

Central.

This mine is situated midway between the Church and Oakland, and is the property of Rix & Firth of S. F. A tunnel 250 feet long crosscuts the two veins, 200 feet deep. The vein where they are crosscut shows two and 15 feet in width. The owners have just had a trial crushing of the ore made at the Oakland mill and its value will determine the working of the mine. Mr. B. E. Carter is in charge as superintendent.

The Church Union.

This plant has been dismantled and nothing but the buildings remain to tell of its former value. The history of the mine is good, and serves to stimulate the owners of other locations on the same vein. The name of the mine was changed to the Springfield, but is better known as the Old Church mine that turned out the yellow metal so freely in days gone by.

The Church Mine.

This mine joins the Old Church Union on the north. The mine was formerly known as the El Dorado until Mr. Church came into possession and organized the Church Gold Mining Co. The similarity of name has led many to suppose that this and the Old Church Union were the same. The Church was opened in the '50's and a large amount of gold extracted from the surface rock. The property then lay idle until 1886, when a shaft was put down to 400 feet. In 1887 a three-compartment vertical shaft was sunk to 650 feet and a crosscut of 80 feet run east to the vein, which is here 11 feet wide. The last 6000 tons of ore milled from the mine gave an average of $18 36 a ton. The present mill is of 10 stamps and three Frues. Mr. James Richards, formerly of the Clipper Gap Iron Works, is Supt. The property is owned by T. R. Church (president), Baker & Hamilton, W. W. Montague and J. H. Neff.

The Equator

Is half a mile south of the Church. A tunnel has been driven 1300 feet, crosscutting five ledges, running from 12 to 60 feet in width, 500 feet deep. On each vein a drift has been run 100 feet. The ores have been tested and by millruns give from $8 to $15 a ton. A 40-stamp mill will be erected within the next three months. The property is owned by Minneapolis capitalists; E. B. Burdick, formerly of the Great Sierra of Tioga District, is superintendent.

The Shaw.

This property is west of the other mines and on the dyke. The Shaw was worked in the early days for the pockets alone. Mr. D. M. Morgan took hold of the mine and put a shaft down 136 feet on the east wall of the 140 feet of mineralized dyke or Seam mine. A Huntington mill has been put up and the property will be in full operation soon. Mr. George Hearst is reported as placing the entire 140 feet as a $3 proposition.

The Greenstone.

This mine was formerly known as the Barnes mine. The vein is a contact, and the ore runs high in tellurides. The property is situated west of El Dorado and is operated by Placerville people. At present the mine is idle, but will resume operations soon.

The Pacific.

The main shaft has been put down 800 feet, showing a vein 21 feet in width. The superintendent, Mr. R. Rowalinds, is now preparing to sink an additional 400 feet. The mill is idle at this time. The mine overlooks the city of Placerville and is almost in the city.

The Gentle Annie.

The five-stamp mill is dropping and will soon be increased to ten. The mine is on the mother lode and is situated 1½ miles north of Placerville. The vein is opened by a drift on the vein, 350 feet long. A crosscut of 80 feet has been driven on the vein without reaching the wall. The ore carries five per cent of sulphurets running from $50 to $80 a ton. The ore mills, with sulphurets included, $4 a ton. Another crosscut tunnel cuts four veins of 2, 10, 18 and 12 feet widths. By shafts and cuts the pay on the main lode is proven to be from 10 to 30 feet in width throughout the entire length of the mine. Mr. J. B G. Parlow is superintendent.

The True Con. M. & M. Co.

On the mother lode at Placerville this company is driving a drift on the vein to cut a shoot that produced $300,000. They are now in 2000 feet and will cut the pay shoot 700 feet deep.

Big Tunnel M. Co.

This tunnel is now in 585 feet and is intended to crosscut several hundred feet on the mother lode. The company has already crosscut a large body of very fine slate for roofing purposes. A Boston company has now taken hold of the property and will put it on its feet.

Gravel Mines.

The Rodgers mine on Smith's Flat, the property of Col. W. K. Rodgers of Sonoma, is in very rich gravel at this time. The pay is on a bench on the east side of the channels. The pay is 150 feet wide and runs from two to three feet in depth. A small piece of cement no larger than a guinea egg yielded $14 in gold, and another lump of dirt weighing about 10 pounds gave $20 in gold. These were pieces of gravel handed Mr. Rodgers by the miners, on the day of my visit, while he was passing through the workings. Gold can be seen all through the gravel. The superintendent, Mr. D. N. Coffin, put the average value of the gravel at $5 a car of 1000 pounds. The gold brings $20 an ounce.

The Linden cement gravel mine of Smith's Flat is also running.

The Cedar Ravine cement gravel mine is running ten stamps. The other gravel mines here closed on account of surplus water, but will soon be in operation. Mr. Landaer is driving a long tunnel to tap the extreme bottom of the channel.

Grizzly Flat.

The Morey mine is running 10 stamps on $40 ore. The Mt. Pleasant is being put in shape and will soon be reopened.

The Pleasant Valley mine with a shaft 230 feet deep, on a vein from three to six feet of ore running from $13 to $15, is not being worked. This is the property of Mr. H.S. Morey of Placerville. The vein carries a large percentage of sulphurets which go as high as $200 a ton.

Roofing Slate.

El Dorado is fast building up a reputation for the value of her roofing slates. The mines have not been able to keep up with the demand.

The Chill Bar Slate Company is located three miles north of Placerville, on the south bank of the South Fork of the American river, Messrs. Motherson & Perine proprietors. The slate is opened by two benches. The lower has a face 75 feet deep and 100 feet wide. The upper bench is just started. When these benches are run 1300 feet the quarry will have a face of 700 feet. The slate will be worked in 40-foot benches. The property consists of 40 acres. At present the owners are turning out 150 squares a month, one square representing a space 10 feet square on the finished roof. The slate brings $7 a square delivered at Placerville. The quality of the slate is of the best. The quarry has furnished the slate for the Berkeley Deaf and Dumb Asylum, Insane Asylum at Napa, and large amounts for the use of the S. P. R. R.

The California Slate Co. property parallels the Chili Bar. The property is being opened by Mr. E. Bird, the superintendent. The property is owned by the American Bridge Co. The mine is shipping 150 squares a month, but will soon be in shape to turn out double that quantity. The face is 200 feet wide and the property 900 acres in extent. The company furnished the slate for the Stockton courthouse and supply the S. P. R. R. Co. with a large amount. I will give you more from this county next week. E. H. SCHAEFFLE.

Mines and Prospects Around Shoup, Idaho.

EDITORS PRESS: — Considering the short period since the mines in this district were first discovered, and the amount of gold bullion they have since produced, together with their present isolation and the prospect of a railroad coming through here in the near future, a brief description of their development and surface indications may be of interests to the mining public.

This camp is situated on the Salmon river in Lemhi Co., Idaho, about 45 miles below Salmon City and 125 miles from Butte, Montana. The principal feature of this district is the Kentuck mine, which is the property of the "Kentuck Mining Co." of Salt Lake. This vein was first discovered in 1883, and has since produced, according to reliable authority, $500,000 in gold, and is developed to a depth of 800 feet on the dip of the vein. The present owners paid $17,000 for the property when there was no development on it excepting two small open cuts, but it showed a strong vein of rich free ore from the start. They first developed it 100 feet deep by running a short adit tunnel and drifting both ways on the lead; then they built a one-stamp mill and two arasta heds on Boulder creek, 1½ miles distant from the mine. By sorting the ore they made it work by this process, $50 per ton, and took out enough money to pay the first cost of the mine and develop it to a depth of 300 feet; then they built a complete ten-stamp free gold mill, which is also run by water-power, using about 200 inches, under a 90-foot head, on a five-foot Pelton wheel.

This mill has run continuously for five years, working the ore just as it comes out of the lead without sorting. It is a hard white quartz that averages about $12 per ton in free gold, and also carries a good per cent of rich concentrates. There are immense reserves of ore in sight and the company contemplate building a 60-stamp mill this summer, right below the mine, so as to save the cost of hauling the ore. The vein is a fissure with a northeast and southwest course, and dips with the hill toward the southeast at an angle of 45 degrees. The formation is "gneiss" with a predominance of coarse feldspar and black mica arranged in horizontal layers, which gives it a wavy, laminated appearance. There is also a succession of large dykes of birdseye porphyry and hard blue-black syenite running through the country, two of which cut the vein, causing a fault of 20 feet in one and 50 in the other. The mine is developed by tunnels driven into the lead, about 150 feet apart, one below the other, which are all connected by drifts and raises. There are two main chutes of ore called the East and West. The East chute does not come to the surface and was discovered while hunting for the West one after a fault. They both increase in lateral extent as depth is attained, and on the lower levels come together, forming one continuous body of ore for 700 feet in length, with good ore still in the face of the southwest drift. The vein on the lower level will average ten feet thick, which has been thoroughly tested by stoping out a month's run at different places the full width of the lead, which was found to yield a handsome profit. It is just 3000 feet from the croppings of the mine down to the river, on the surface, and by keeping in a gulch which runs straight down, it would have an average grade of about 35 degrees, and as the lead has a pitch of 45 degrees square toward the river, it would not require a very long tunnel to tap this lead at a depth of about 2000 feet on the dip. About 100 yards below this tunnel site, the Salmon river has a fall of five feet in a hundred, which could be made to furnish very cheap power. The company owns 12 full claims, all connected, three of which are patented, and all show more or less quartz at the surface. With so much ore in sight and such natural advantages for development, and the gold rapidly gaining in fineness as depth is attained, it is safe to predict that this mine will be producing bullion a generation hence. About a quarter of a mile east of the Kentuck is

The Grunter Mine,

Which was fully described in these columns last March, so it will not be necessary to give it in detail again, but to give an idea of its productiveness it might not be out of place to state that one miner alone this spring broke and wheeled a short distance from an open cut on this mine, 300 tons of quartz in just three months. Said rock is being milled at the present time and averaging $10 per ton in free gold.

The Speculation Mine

Is about 1000 feet south of the Grunter mine, running parallel. It is a two-foot vein of the same character of ore, developed by a 40-foot shaft and two short tunnels. There is an arastra connected with this mine which has a 24-foot hurdy-gurdy wheel and a 12-foot bed. It has produced considerable ore that averaged $40.

North of the Grunter, about one mile, is located the Gold Crest and Monolith claims, both on the same vein, which crops out a long distance from two to four feet thick. It is developed by short tunnels run on the vein, and has produced several hundred tons of ore, which was worked in an arastra right below the mine, and run all the way from $20 to $100 per ton.

Clipper and Bullion.

On the opposite side of the river and about the same altitude as the Kentuck are the Clipper and Bullion claims. This was a blind lead, and was discovered two years ago. It has about the same course and dip as the Kentuck, but being on the opposite side of the canyon, dips into the hill; yet it is very steep quite a way below the mine, and it would not take a very long adit tunnel to cut it a good depth. It is developed by two levels run on the lead, which are connected by a winze and short adit tunnels, and show a well-defined vein of free-milling honeycombed quartz, about 300 feet in length, 120 feet deep in the vein and from 18 inches to 3 feet thick.

One hundred and fifty tons taken from the upper level of this mine averaged $64 per ton in a custom-mill. The owner, Mr. Eli Suydam, is at the present time erecting a Kendal mill with a capacity of six tons in 24 hours, to work his own ore.

About one mile south of the last named mine and on the waters of Pine creek, there is

A Group of Claims

Owned by the Pine Creek Mining Co., a Philadelphia organization. There is a 10 stamp quartz-mill run by water-power, a steam sawmill, and a whole lot of mismanagement connected with this property. The principal vein is a true fissure, 2 feet wide, that works about $18 per ton in free gold, and carries some very high-grade sulphurets. If it was developed a little further and properly managed, it ought to pay a handsome profit, but the property is lying idle at the present time.

The Lexington and Virginia

Veins are located two miles farther up this creek. One is three feet and the other 10 feet wide, developed to a depth of about 50 feet. The smallest vein is said to average $40 per ton in free gold; the other is low grade. There is a one-stamp mill in connection with this property which has pounded out over $20,000.

Copper Glance.

On leaving Pine creek the formation changes to a metamorphic slate. After climbing up a steep gulch to the south, we come to the Beaver creek divide. There, at an altitude of 6500 feet, in a burnt-up slaty formation which is very much threaded with veinlets of white quartz, there is a claim located called the Copper Glance. It is a brick red and brown porous quartz that shows a few grains of native copper in the pan. It crops out at intervals for 1000 feet. In the center of the claim there is a cut run into the vein which shows it to be about 8 feet thick. There are about 10 tons of ore piled on the dump from this cut, which is a black massive silicate of copper, with cores and streaks of purer metal. The whole pile is said to average 30 per cent, but it is easy to sort out soft pieces of copper glance that will run 80 per cent; it also carries both gold and silver to the value of $20.

It is about three miles from this mine southwest to the

Big Creek Hot Springs.

These springs come to the surface in the bed of a deep gulch, in a granite formation. The gulch is dry for two miles from its head; then there is a small spring of ice-cold water flowing about six miner's inches, and 100 yards below are the hot springs, 15 in number, which have an aggregate flow of about 40 inches. They are all clustered together on about half an acre of ground and the water in some of them is intensely hot. It will boil most anything put into it. One of these springs bubbles up in the bottom of a small cavern, which is formed by the sediment accumulations from two springs above it and just about big enough for a man to stand in. The walls are encrusted with beautiful mineral tints of green, pink and yellow, and from the cavities issue gentle puffs of steam with clock-work regularity.

A Failure.

About two miles below the springs where the water enters Big Creek, there is a camp called Dynamo, after a defunct Arc Light plant, which is the property of the Beaver Head Hydraulic Co. This is another example of rank mismanagement, and an eyesore to a creek that was never given half a show to prove its value.

This company was organized in Albany, N. Y., by some New York stock-jobbers, who, of course, undertook to run the works themselves in place of hiring a competent engineer. The consequence was they spent $150,000 and accomplished absolutely nothing. All the bars and points along this creek carry coarse gold, some of which has been worked by drifting and

rocking, and paid from $3 to $5 a day to the man; and there is a tributary putting in about 10 miles above the works which has produced $12 000,000 in placer gold since 1867.

About five miles south of Dynamo there is a lead vein located, called

The Henrietta.

It is 18 inches thick of solid, high-grade galena that melts readily in a camp-fire, but it is low grade in silver. The formation is a micaceous, slaty rock, very much stained up with red oxide of iron and looks very favorable for mineral. It is three miles below Dynamo to where the main creek enters the river at a point eight miles below Shoup; and a little farther down on the opposite side Owl creek puts in. Near the mouth of this creek there is a claim called the Paymaster. This is a vein of white quartz in a granite formation, which crops out for a thousand feet in length from three to four feet wide. There is a shaft down 10 feet, which shows some very pretty specimens of black sulphurets of silver and specks of native gold.

Traveling Through a Basin Country.

Which is studded with millions of feet of the finest pine and red fir timber a man could wish to see, at the head of the East Fork, we come to a prospect called the Esmeralda. This is a ten-foot vein of fine-looking red and brown honeycombed quartz, that pans well in free gold. There is a 20-foot shaft down, and an average sample across the bottom of it assayed $23 in gold and silver.

The Orr group of claims are situated about four miles north of the Esmeralda. There has been considerable work done on this property, which shows some large veins carrying massive, fine-grained pyrites of iron and copper, and some galena and antimony which is said to be very rich in silver.

About six miles east of here, on the headwaters of Spring creek and near the main divide of the Bitter Root range there is

A Camp Called Lentville.

There are about 30 claims altogether, which are large veins of concentrating ore, from 10 to 50 feet thick. The principal one is called the Lent mine, and is developed by about 200 feet of tunnel run on the lead. The ore is a mixture of copper pyrite, galena and antimony, with considerable specks of gray copper. It is said to assay from $20 to $2000 in silver, and is owned by a Missoula company. It is eight miles from the Lent mine to the mouth of the creek, where it enters the river two miles above Shoup, on both sides of which are located several prospects of minor note. The formation is granite and porphyry and the ores most base copper and silver, but some of them show a little black sulphorets of silver.

This district might be said to be constructed on an angle of 45 degrees, but it is well watered and heavily timbered, has a big variety of minerals and formations, with a stretch of country for 100 miles north and west, which has hardly been looked into. With the developing stimulus the "Midland Pacific" railroad will bring, it is destined to play an important part in assisting the embryo State of Idaho to forge ahead to that enviable position in the production of precious and useful metals of which her energetic neighbors now boast.

Shoup, Idaho. R. BELL.

Ophir District, Placer County.

[From Our Own Correspondent.]

At Ophir the Hathaway is dropping 20 stamps on $8.50 ore. The concentrates are saved by the Woodbury concentrator, which, after a competitive trial with another prominent machine, was given the preference. I was promised the full particulars of the test, but it has not been forthcoming. Suffice it that Messrs. Valentine gave their order for the Woodbury machine, after a thorough trial of the Victor, Gorrier, Frue and Woodbury. The shaft in the mine is now down 250 feet on a 2½ foot vein in granite. Mr. G. T. Taylor, formerly of the Kennedy mine, Amador county, is now superintendent. The property is owned and operated by the Valentine Bros.

The Eclipse mine is proving a bonanza to the fortunate owners. Each day sees richer bodies of ore exposed. Should they continue, the mine will "eclipse" anything in the State. The mine is opened to a depth of 300 feet by shaft, with levels run 225 feet. The vein runs from 2 to 4 feet in width. The veins cut the country rock at an angle of 45 degrees, cross-cutting granite, porphyry and slate. The ore runs from silver to free gold, but on the average contains one-third silver and two-thirds gold in its values. The mine has now ten stamps, but will soon be equipped with ten additional stamps. Mr. C. A. Poage is the fortunate president, with Mr. J. B. Patterson (an aspirant for the position of Governor of the State) as superintendent. If Mr. Patterson can succeed as well in his gubernatorial aspirations as he has in mining, he bids fair to eclipse his numerous competitors. Ophir has a bright prospect, and this once abandoned camp bids fair to outstrip her early prosperity. I did not get into the other mining sections of the county, so cannot now give any description of their present prosperity. E. H. SCHAEFFLE.

ALL the leading mines on the Comstock lode are looking well, all having in sight an amount of ore sufficient to cause their several superintendents to feel quite at ease as regards supplies for milling.

The Gold Belt of Northern California.

Ancient River Channels and Gravel Deposits.

NUMBER IV.

[Written for the MINING AND SCIENTIFIC PRESS by JAMES M. TALBOTT, Shady Run, Placer Co.]

The first point where there is any evidence of the existence of these conditions is observed on the ridge southeast of Auburn. Here is a considerable deposit of lava. Whether or not it covers an ancient or modern channel, it is about on a line with the course of the lava flow down the Forest Hill ridge. The upper foothill section appears to form something of a terrace or bench between the "ditrns" and gold belts and is about 20 miles wide, distinguished by low rolling hills, little valleys and small canyons, and its utter barrenness of gold diggings between the main rivers.

There are a few quartz ledges that carry gold; there is not a vestige of live; no ancient channel nor gravel deposits; no ravine or canyon diggings that ever paid grub, within its bounds, outside the rivers. All the mining in this section has been confined to the bars and benches along the rivers and in the river-beds, where some very rich claims have been worked. The bedrock formation is apparently the same in the three sections. In the lower foothills are rich quartz ledges and some rich gravel deposits; in the gold belt section, rich channels and gravel deposits.

Some of these peculiarities may be accounted for, but some "scientific guss" will have to explain why there are no gold diggings in this intervening section.

The topography of the country indicates that the

Ancient River of the Forest Hill Ridge

Passed through a deep narrow gorge and made a sharp bend to the southward, in the vicinity of Spring Garden, about where it left the gold belt and entered into the upper foothill section. The channel is partially filled with the cement and debris from the mud flow, and perhaps a portion of lava, when an excessive and long-continued flow of lava set in and completely blocked up the channel and formed a permanent dam in this narrow gorge. This excessive lava flow, then, is the prime cause that puts in active operation all of the other agencies involved in the great change. The water was diverted into some lateral canyon or large tributary, free from lava. Here, then, commenced the erosions in the gold belt, that scooped and cut out the modern basins and channels and filled them up with bowlders, gravel and gold, from the ancient channel; detritus, pipeclay and all kinds of material from the surrounding country. The first effects of this method of modern channel erosion and gravel deposits are observed on the south side of the ridge about Spring Garden and at Todd's Valley. Here is an extensive gravel deposit in a modern channel or basin. After this was formed, a flow of lava blocked up the outlet and further filled up the ridge. Then a similar break occurred on the north rim and cut out a modern channel, and formed the gravel deposits at Yankee Jim's and Brushy Canyon, and thus, by this method of alternating lava flow and floods, the ancient channel was filled up and the modern ones cut out and filled up in like manner, as the lava filled the ridge. Where the conditions were favorable, gravel deposits were formed. Along the south side of the ridge the deposits about Forest Hill, Bath, Volcano and Michigan Bluff were formed by this same method. Above Michigan Bluff the ancient channel crosses through to the north side of the ridge, where it is blocked up to above the Brimstone Planes. The indications are that

The Lava then Ceased to Flow

For a long period of time — a period long enough for the floods to cut out a modern channel down the Iowa Hill ridge and form the extensive gravel deposits along that ridge, and carry down the millions of gold found in them and the adjacent rich canyons. When the flow again set in and this channel was blocked up and capped with lava, we can account for the wash not being so heavy and extensive on this ridge as on the Forest Hill, by the displaced waters of the main tributaries finding an outlet around the lava dam on the Middle Fork side into some lateral tributary unobstructed with lava, running on about the same course of the present Middle Fork. The vantage for the erosion of this modern river is obvious, when we consider the change of level occasioned by the subsidence in the valley sections, which largely increased the grade, an important condition of erosion. From the course of the

Ancient Channels Through the Gold Belt

To the southwest, it is evident their gravels were dumped along the lower foothill section in the vicinity of Auburn, Newcastle, Ophir and the surrounding country, until the waters were diverted into some modern eroded channel. It is possible that the channel was blocked by the lava just above Auburn and the waters displaced into the present river, where, at the junction of the North and Middle Forks, the river makes a short bend to the south and has cut out a channel several hundred feet lower than the old one. From this point the modern erosions have followed the course of the ancient channels through the upper foothill section to the lava dams in the gold belt, which will account for the absence of any channel or gravel deposits in this section. The

Effects of the Deep Modern Erosions

Are manifest all along this section by the high, abrupt hills on either side the river, and the numerous extensive benches and bars, with a deposit of 50 feet of bowlders and gravel, high above the present river. The conditions of erosion here established continue throughout all time, and extend from the low valley section to the volcanic region of the Sierras, in the mountain section. In regard to this extensive region, lying between the gold belt and the summit, the indications are that the deep erosions of the present rivers through the gold belt have given the mountain section the steep grades that carried away the principal portion of the large tributaries of the ancient river and deposited their contents in the numerous modern canyons. It is a well-known fact that all the mining done above Town. R. 12 E. (the gold belt) is confined to remnants of small channels—in some instances capped with lava—and in the numerous large canyons of this section. The

Facts Obtained From Actual Workings

And the present topography of the country indicate that the Pliocene river of the Middle Fork divide—like the present rivers—had tributaries running from the north, east and south; that they drained all the country now drained by the Middle Fork, some portions of the North Fork and possibly portions of the South Fork; and that they made their debouch from the mountain section, in the upper portion of the gold belt, thereby forming one grand river, whose channel received the gold brought down, by the steep grades, from the section above.

The foregoing detail of facts shows conclusively that all of the

Agencies Were in Active Operation

At the same time. The volcanoes of the Sierras furnished the lava that dammed up the ancient rivers and displaced their waters. The vast subsidence in the valley section at the same time gave the vantage for erosion. This great change was not sudden, but must have endured for centuries of time. Neither was it local, for the same conditions are observed throughout the whole western slope of the Sierras for 300 miles or more.

Had it not been for this excessive lava flow, we would have no ancient channels 2000 feet above the modern rivers, the modern erosions would have followed those channels, the same as in the upper foothill section, and the miners of to-day would be delving in the deep mountain gorges for this same gold that they are now taking out through long and expensive tunnels under those lava-capped ridges. In regard to

The Modern Gravel Deposits,

The fact of the channels of the two main ridges uniting above the Brimstone Planes indicates a common source, and the fact that there is not a gravel deposit on the divide but what can be traced directly under or to the lava capping, which shows conclusively that all the deposits between the North and Middle Forks not only have a common source, but form an independent system. I have been thus definite in outlining this theory on the Middle Fork divide, to show that it is in harmony with developed facts, and accounts for the varying conditions. If it is correct as to this divide, why not on other lava-capped divides of similar formation and like conditions?

The North Fork Divide.

If the Middle Fork divide contains an independent Pliocene channel and system of gravel deposits, as herein described, I propose to show by the same line of indications and facts that the North Fork divide contains a similar one. This divide embraces the country lying between the North Fork and the South Yuba river, and is almost the exact counterpart of the Middle Fork divide in general outline and topography, differing slightly in detail. Bear river separates it into two prominent ridges in the same way that Shirt-tail canyon separates the Middle Fork divide. The country between the South Yuba and Bear river is the Nevada Ridge; that between the North Fork and Bear river I will term the Shady Run Ridge.

[If no new ideas are advanced in this article, I will introduce some new names.]

Mr. Bowman is the best authority on this subject that I have ever read. In regard to what I call the Shady Run Ridge, in the C. P. R. R. Survey, he says: "You will follow in your walk a mountain crest as continuous and regular on top as a railroad embankment. It is the volcanic divide or capping; an ancient mud and lava flow that filled up the extinct rivers' bed, which gave it direction, covering in and sealing up within the bedrock rims the accumulated Pliocene gravels, and displacing the water into the new channel of the present time, the yawning gap of the North Fork of American river 2000 feet beneath your feet."

Mr. Bowman gives us no idea of the course or extent of the extinct rivers' bed that gave the mud and lava flow direction.

There is not a lava-capped ridge in the State where the conditions are as favorable for tracing the course and extent of the Pliocene river channel, with the same degree of certainty, by the surface indications, as this one. The C. P. R. R. excavations along the rimrock, nearly the entire length on one side where the mud (or cement) and lava are seen inside the rim rock every mile or so. On the other side, Towle's narrow-gauge road and the Gold Run branch of the South Yuba ditch, where the same conditions are observed, though not so prominent. Following a modern method, we will select a commission, composed of some eminent geologist and noted mining experts, to investigate the facts and

Observe the Conditions.

If too lazy to walk, which is generally the case with commissions, we will board the train at Towles and sketch an outline of the facts and conditions from the platform of a car on the overland flyer.

This is about on the lower edge of the great serpentine belt. Just after starting up, the geologist will notice the natural appearance of the bedrock in the cut on the north side of Canyon creek. On the south side we pass through two short cuts of the same formation. He will particularly note that the changed condition denotes the effects of extreme heat from a heavy deposit of lava on the point above, a few hundred feet to the east. This fact has not been noted in this connection heretofore. The mining experts will observe that this is the north rim of the Pliocene channel. About half a mile to the south we cross through the ridge in an open cement cut. Here the rim-lava and a portion of the cement has been carried away on either side by the modern erosions. Running alongside of this cement about half a mile, we come on to the south rimrock just below rock cut. From here the track winds around and cuts through high bedrock points for about two miles. Within this distance the cement, capped with lava, is observed in several places some distance back from and high above the road. At one of these places the cement was quarried out for building culverts under the railroad.

As we move along you will notice a projecting point of bedrock 300 feet above the track, where the road leaves the river bluffs and curves around to the north just below Shady Run. On passing through two or three low bedrock cuts, we come on to an extensive flat formed by big slides from the ridge. The road curves around the upper side of this flat for about a mile and a half. The flat extends from the ridge about half a mile on to the bluffs of Bine canyon. The rimrock along here has been carried away for from 50 to 200 feet, and in one or two narrow breaks 350 feet below the railroad. Here, at an altitude of 4150 feet, is the nicest place and finest climate in the mountains. No finer apples, pears, plums and cherries are grown in the State.

As we approach the station at Shady Run, you will observe the cement crops out above the road in a small ravine near the railroad woodshed. This body of cement is more than 200 feet thick, and extends through the ridge under the lava cap to Canyon creek. We are right at the station now, and are passing over a tunnel run in the cement 200 feet perpendicular below the track. I will refer to this tunnel hereafter. About three-fourths of a mile above the station, at the upper end of the big flat, the road curves to the northward and strikes into the most wonderful section on the whole line. The most acute observing geologist or mining expert, looking at the tall pines, the scrubby oaks and underbrush that covered these rugged points, would not have a remote idea of the true conditions, as revealed by the railroad cuts 100 feet beneath the surface. Within the brief limits of one-half mile here, we can read the history of events as they transpired thousands of years ago, and define the method. In the first cut you can see in a measure

The Extent of the Mud Flow.

By looking down to the right 100 feet or more, over a cliff of this mud cement, you can see the rimrock. About 20 feet above the track, on the upper side, the lava cap comes on to the cement. The line of junction is as prominent as if made by a painter's brush.

A few hundred feet farther up, the road curves through a steep, narrow point in a cut about 75 feet deep. No description of the deposit in this cut can give a correct idea of it. The banks on either side resemble the ruins of a tumble-down piece of huge masonry, built of masses of float bedrock; big, rough, angular bowlders, filled in around with all kinds of smaller rock and all cemented together with lava. The bottom deposit in the next cut, a short distance above, is of the same material, put together in the same way. About midway of this cut is a deposit of 20 feet of small, smooth-washed bowlders—cobbles, gravel and sand, with a few rotten granite bowlders, five feet in diameter; showing evidently the action of water from a granite wash. On top of this granite deposit has come another lava flow, and a big rush composed of the same kind of material as that underlying it. At the upper end of this cut you will *notice particularly* a low sag in the ridge. There is where the Cedar Creek ditch runs in a tunnel cut through the lava cap and dumps the water into Canyon creek, where Towle's narrow gauge-road runs about on a level with the C. P. R. R., not more than half a mile distant.

Here we make a sharp curve to the east and soon enter a short cut, where the rimrock shows 20 feet above the track on the right. On the left from the level of the track it pitches abruptly back under the ridge. The deposit in this cut is composed of an irregular confused mass of all kinds of material found in the ridge. Large masses of lava imbedded in and covered over with big, smooth washed bowlders, gravel, sand, slickens and large-sized, round water-worn cobbles as can be found on any modern river bar.

(*To be Continued.*)

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Alameda.

COAL.—Livermore *Herald*, June 26: There are now employed at the Eureka Coal mine 18 miners, 12 shovelers, four mule-drivers, four dumpers and utility men, one blacksmith, three carpenters, one engineer, one fireman, three teamsters, and a superintendent. Total, 48. There are also a few substitutes. The schedule of wages paid is as follows: shift foremen, $3.50 per day; miners, $3 per day; shovelers and others, $2.50 per day. The miners work in three shifts of eight hours each; all the other men in ten-hour shifts. The pay-roll amounts to nearly $4000 a month. The work is now continued without intermission, day and night, and Sundays as well as week days, in all three of the tunnels. Excellent progress is being made,

Calaveras.

WEST POINT.—Cor. Calaveras *Chronicle*, June 28: The chlorination works are making a run on the Blazing Star sulphurets. The Hurley and other mines are all reported as working steady and doing well. Fred Greve, owner of the Black Wonder mine, is taking out some good ore which keeps three teams hauling steady to his mill.

Fresno.

AROUND HILDRETH.—Mariposa *Gazette*, June 28: The mining region around Hildreth is again active. Prospecting is going on vigorously throughout the entire neighborhood, although two of the large mines, the Abbey and the Hildreth, are permanently closed. Green Hitchcock has bonded the Morrow mine. The Wilson, which assays $1500 to the ton, is not running at present, but arrangements are being made to open it permanently. If sufficient capital was expended on the numerous veins and locations in this vicinity a handsome interest would be returned and good times would soon be assured us, but most of the mines are owned by men of small means who cannot expend enough to enable them to reap much benefit from their labors. The Zebra, which, under the efficient superintendency of Mr. Brett, made such fine clean-ups last summer, is again doing well under Supt. J. Rodgers, lately from San Jose. The mill is running night and day, crushing 16 tons of ore daily Thirty men are employed, and should the present bright outlook continue, twice that number will be given work. The company are jubilant over the prospect of golden linings to their pockets, and the whole neighborhood is rejoicing and having a share of the prosperity.

Mono.

AT BODIE.—Lundy *Index*, June 26: Supt. Macey will thoroughly test the proposition of working Bodie low-grade ores, of which immense quantities are obtainable. If he succeeds in milling them at a profit, it will be necessary to handle them on an extensive scale, and keep in operation all the available crushing apparatus in the vicinity. This one problem satisfactorily solved at the old Standard, it may fairly be presumed that the Noondays will be reopened and made to give up something from the vast ledges of low-grade quartz known to exist in them, and other mines will follow suit, there being a dozen places in the district where material may be found that can be made to pay, if the Standard experiment is successful. This will necessitate the employment of a large number of men, and the camp will be lively once more.

Nevada.

MEADOW LAKE MINING DISTRICT. — Sierra City *Tribune*, June 25: Parties here who are interested in Meadow Lake (Nevada county) mines report that the snow will not be off up there before the first of August. Considerable work was done there last season. The Keystone Mining Co., composed of Sacramento and San Francisco parties, had miners running their tunnel ahead on contract during the winter. A number of practical miners of this place, who have been operating up in that district, have great faith in the mines there, and are confident that they will ultimately be successfully worked. The gold is undoubtedly there, they say, and one of these days the genius of man will discover a way to save it.

RICH ROCK IN THE PEABODY.—Grass Valley *Union*, July 1: Yesterday evening Superintendent Tilley brought to town some beautiful specimens of quartz that had been struck during the day in the shaft of the Peabody mine. The gold showed among delicate quartz crystallizations, and one piece of wall rock was shown which had a narrow band of quartz running through it that was studded with gold. Beside the specimen gold in different pieces of quartz, the gold was seen mixed with sulphurets. The specimens attracted much attention, as they were the handsomest that have been taken out in the district for some time. They were taken out in sinking the shaft, which is now at a depth of 215 feet, and it is the first time that gold-bearing quartz was ever found in the shaft. The ledge is showing nearly four feet in size. This rich find is very encouraging for the future of the Peabody, and shows that Gold Hill yet retains its old-time riches.

HUDSON MINE.—Grass Valley *Union*, June 29: The Hudson mine, located on the banks of Deer creek, near the old Hudson House, said mine used to be called the Scandinavian, has been idle for the past week on account of the burning out of a boiler. Yesterday, however, work was resumed. During the stoppage water rose to a considerable hight in the shaft, but it will be but a few days before the shaft is pumped out and the work of sinking resumed. There is a San Francisco company operating the mine, and developments recently made gives them every encouragement to go ahead with the work.

THE IDAHO NEW LEDGE.—*Tidings*, June 25: Ten stamps are running on the ore from the large new ledge in the 1700-foot level of the Idaho and the returns are up to the average of Idaho ore. No idea of the extent of the chimney, or deposit, has been gained. The workmen in the drift are now engaged on a raise. Mr. John Coleman informs us that the incline is to be given greater depth, indications warranting the belief that when this is done the bottom of the shaft will not be far from the new ledge, provided the discovery proves to be a ledge and not a mere chimney, something that can be better passed upon a year hence than now. It may be that it is a chimney—one of immense proportions.

MANHATTAN MINE TO BE REOPENED.—Grass Valley *Tidings*, June 30: Thursday of this week teamsters will commence hauling machinery to the Manhattan mine, just above and adjoining the Pittsburg and near the famous Sneath & Clay mine, in Nevada district. A. S. F. company represented by M. L. Elliott will conduct the operations. The machinery has been obtained from John M. Thomas and others, and workmen to-day commenced to take it off the Roach claim, two miles below Grass Valley, and arrange in lots for transportation. It is of power sufficient to enable workings to the depth of 800 or 1000 feet. Although in Nevada district, the Manhattan ledge is not in the characteristic granite formation, but in slate, as in this district, and the ore is free milling. The mine is 300 feet in depth and the ledge from two to four feet in size, yielding from $10 to $40 per ton. It was shut down less than 20 years ago, the company losing heavily because of the destruction of the works twice by suction by fire. The present company will utilize water for power, being but 2000 feet distant from the South Yuba Company's upper ditch and 190 feet below its level.

GOOD PROSPECTS AT THE MENLO.—In the Wisconsin incline of the Menlo property now being operated by a syndicate under hood, Mr. E. A. Wiltse, superintendent, a two-foot ledge was cut Friday at a depth of 72 feet. The ore is highly mineralized and shows gold freely and is all pay rock. The management expected to find a ledge at about the point where the discovery was made, but that ore of such evidently good grade would be uncovered was unexpected. It is undoubtedly the shoot worked in 1857 and 1858, when high-grade ore was extracted. The Homeward Bound shaft, on the same property, has been cleaned out, placed in good repair and sinking inaugurated.

ENCOURAGEMENT AT THE LAFAYETTE.—The ore from the 18-inch to 24-inch ledge in the face of the Lafayette tunnel is of such encouraging appearance that the management has resolved to go back and run a drift that will give additional backs of 300 feet. Considerable ore has been extracted and a crushing will soon be made. Operations on the Ben Franklin in the hands of the same company, a Chicago syndicate, have been delayed by the molders' strike in San Francisco, necessitating the casting of machinery in this city in addition to that originally arranged for.

OPERATIONS ON THE SEVEN-THIRTY.—Messrs. Rawling, McLachlan & Co. are making good progress down on the Seven-Thirty ground, Deadman's Flat. They have put down, with a windlass, an incline through the old works a depth of about 90 feet. The ledge will be found at a depth of about 120 feet, and water is now to be contended with.

San Diego.

JULIAN DISTRICT.—Cor. San Diego *Sun*, June 27: The Owens mine is situated in the town of Julian, and has been worked for a number of years. The mine for some time past has done little to speak of, and the pump getting out of order the shaft was allowed to fill with water. But with all its setbacks, brighter times are beginning to dawn on the owners. The new Cornish pump has arrived and is being placed in position, and will be ready for use in two or three days. It has a capacity of 25,000 gallons per hour. The main shaft is down 400 feet, with a rich body of ore at the bottom, in fact, the stuff is rich at all the openings. Nick Campbell is foreman of the Owens.

BLUE HILL.—The management has just finished cleaning out the top level, which will give them stoping ground for 300-feet, and will be used as an air shaft for the lower level, where some of the richest ore ever taken out of a mine is to be seen.

HELVETIA.—The brothers of Ex-Governor Bartlett were the first owners of this property. In former days it was looked upon as one of the best paying mines in the district. The present management has sunk a new shaft and struck very good pay rock and a good body of it. A number of veins concentrating at the bottom of the shaft constitute a formidable breaster of ore. At present the company is cleaning and timbering the old shaft and when this work is finished a drift will be run intersecting the new works.

THE HIGH PEAK MINE. — This property is owned by Ferguson, Garland and Mark, and is an old-worked mine, but for the last few years little work to speak of has been done. Until recently the property was bonded to Barnett & Co., of San Diego. This company is running two shifts and driving the lower level with all possible speed, the top level being in some 400 feet. In this level there is a body of ore fully three feet in bulk the character of which is remarkably nice and I have but little doubt that it will assay all the way from $8 to $14 to the ton when the lower level is in the required distance. Stoping and sinking will be the order of the day.

THE EAGLE.—This is owned by Crays and Mallock. These gentlemen have rested on their oars for some time, Uncle Mallock being ill, work had to be suspended, but the present prospect is more cheering, and active work will be resumed on the Eagle.

THE VAN WERT MINE.—This property is owned by Ferguson and Wilson, and is a real good little mine, with very rich rock in sight and a large proportion of it carrying free gold. The Oak Grove and Genevieve mines are owned by Pete Hanson and Walch Hanson. The latter is one of the most experienced miners in camp and has resided here for a great many years.

Shasta.

CALUMET.—Redding *Free Press*, June 28: The south fork flume of the Spring creek ditch, which furnishes power for the Calumet works and which is 220 feet long and 40 feet high, was rebuilt in 11 days, with water turned through. The stamp-mills of the Calumet Co., also the two dry-mills working the Paul dry amalgamating process, are all running. They expect to fire up their furnace after the 1st. Charles Thistlewait and Frank Cunningham are at work on their tunnel opposite Middle Creek station. They have a three-foot ledge, and the quartz shows up splendid. Work on the Eureka tellurium mine is progressing. Philip Scherer was recently elected secretary of the company. The mines on Squaw creek were never in a more promising condition. There are above 100 men at work, and the mills are turning out lots of bullion. The Uncle Sam and the Reilly mines particularly are paying big. The rock in the Sky Blue mine looks better as depth is attained. Some of it is bespattered with gold. This is a rich mine. J. H. Beecher of Anderson was up looking at his mine near B. Swasey's ranch this week. He has 50 tons of ore at the Atkins Reductions Works from which he expects good returns.

Sierra.

THE MOUNTAIN MINE.—Sierra *Tribune*, June 29: Everything is bustle and activity at the Mountain mine. Down on the bank of the North Yuba river, where the grading for the 40-stamp mill is about completed, the big boarding-house is well under head way and will soon be ready to occupy. A large force of men have been put on the road and flume, and the contractors propose to push it through in the time allotted to them. The contract to build the wire-rope tramway has been let to the Trenton, New Jersey, Iron Co. Parties will arrive here before long to inaugurate that work. Sixteen men are employed up at the mine, and everything is being put in shape for such time as the mill is ready to start up, which it is expected will be during the month of October.

ANOTHER GOOD MINE THE VICTIM.—The Alaska Mill and Mining Co., which operated the Alaska mine at Pike City, this county, has applied to the Superior Court of San Francisco for a dissolution of the corporation, which was formed Dec. 1, 1861, with a capital of $10,000,000 in 100,000 shares. The Alaska has always been a good mine and has yielded enough gold to have given handsome profits to the stockholders, if it had been operated upon business principles. Like many other companies who have operated in this county in the past, the Alaska was the victim of its own foolish and extravagant management.

MINING SALE CONCLUDED.—The sale of the Chips quartz mine at this place to San Francisco parties has been completed by the payment of the purchase price, $16 000, over to John Henderson, who was owner of the property. The Chips is regarded here by those who have had opportunities for knowing as being a good mine. The 10-stamp mill is to start up in a few weeks.

Trinity.

CANON CREEK MINES.—Trinity *Journal*, June 28: Last week we made mention of the striking of the ledge in the Bailey mine on Canon creek. The tunnel in which they struck it taps the ledge at a depth of 175 feet. The ledge is 7 feet wide, carries free gold and is rich enough to make any man wish he had an interest in it. It will probably average not less than $40 to $60 per ton, and about half of the ledge is much richer. They are running the tunnel to tap the other ledge, which they expect to strike at a depth of about 275 feet. If this is found as good as the one already tapped, there will be enough ore in sight for a 40-stamp mill. The owners of the Fisher Gulch mine are sinking a shaft on the ledge to the depth of 50 feet. They are now down 25 feet and the ledge looks well. If at the depth of 50 feet the ledge shows up well the owners will put up an arastra and give the ore a working test as the mine is being prospected. They have already begun the construction of a ditch to divert the water from the gulch. The mine, if it proves to be one, is so located that it can be worked cheaply and very conveniently. The latest strike in this district is the McGinty, found last week by Zack Weyand and Dave Thye, in which W. D. Everhart and Chris Meckel of this place are interested. The ledge is about a foot wide, between good walls, and the rock is estimated to go $75 to the ton. The company has another location called Sunday Morning, which prospects well. Work on both of the locations is now being done, and without doubt the company will develop a rich mine. There are several very rich prospects in that district and some of them are under process of development. If they turn out reasonably well according to present indications the Canon creek will be the richest camp in the county in one or two years.

NEVADA.

Washoe District.

ANDES.—Virginia *Enterprise*, June 28: The 420 level north drift from No. 2 west crosscut extended 45 feet, formation quartz and porphyry. On 350 level west crosscut extended to 289 feet; formation porphyry, with seams of quartz.

SIERRA NEVADA.—The west crosscut from the southwest drift on the 630 level is still being advanced in a mixture of porphyry and clay.

BELCHER.—The No. 3 west crosscut from the 200 No. 2 south drift was advanced 24 feet, making its total length 39 feet, and struck the wall at that point. No. 3 east crosscut, opposite it, is out 15 feet, the face in a mixture of quartz and porphyry. The 200 north drift from No. 3 east crosscut is out 42 feet, in low-grade quartz. Have completed timbering the 850 east crosscut and started a west crosscut opposite it, which is out 32 feet in a mixture of clay and porphyry. The 1300 east crosscut has been extended 24 feet, making its total length 136 feet. The face is in soft ground, showing streaks of quartz.

UNION CON.—East crosscut No. 1 on the 1466 level is still being advanced in porphyry and clay.

SAVAGE.—On the 300 level, east crosscut No. 2 from the south drift was advanced 29 feet in vein porphyry. On the 1300 the north drift is advanced 68 feet, and continues in the good ore mentioned last week. During the week milled 455 tons of ore; average battery assay, $20.17. Have bullion on hand amounting to about $20,000.

OCCIDENTAL CON.—Continue to extract gold of good quality from the stopes on the 400 and 450 levels. In the 550 level north line west crosscut the winze is down in a mixture of quartz and porphyry. The 650 level is finding quartz that carries some metal.

IMPERIAL.—The joint Confidence, Challenge and Imperial west crosscut No. 2, on the 1000 level, is out 140 feet, 20 feet having been made during the week. The face is in quartz giving low assays.

CON. CAL. & VIRGINIA.—Are extracting the usual amount of ore from the 1300 and 1500 levels. The raise along the west wall on the 1435 level continues to show some metal. A considerable amount of ore is being extracted on the 1650 level. The usual amount of ore will be shipped to the mills this week, and the average battery assays will be about as heretofore.

CROWN POINT.—The winze from the 160 east crosscut has connected with top of 300 south stope, and shows overhanging clay at point of connection that threatens to cut off the pay ore at that point. Shipped to the mill during the week 809 tons, 1730 pounds of ore, the average battery assay value of which was $17.03 per ton.

NORTH OCCIDENTAL.—Work still confined to repairs.

POTOSI.—The winze below the 930 level is still in ore of a good milling grade. The ore is about five feet in width and shows much strength. All the experts who have examined the development are well pleased with its appearance.

CHOLLAR.—On the 750 level good ore is being mined in No. 1 crosscut. No. 3 crosscut is still showing well as regards formation. Good headway is making in the north lateral drift on the 900 level.

SEG. BELCHER.—The 1000 raise from the No. 1 east crosscut is up 109 feet, having advanced 27 feet during the week. The top is in low-grade quartz. Have completed the timbering of the joint 850 east crosscut, and have started a west crosscut opposite it, which is now out 32 feet, the face being a mixture of clay and porphyry.

HALE & NORCROSS.—Are working on the 500, 800, 1250, 1300 and other levels. At several points low-grade ore is showing, and some of these are likely to lead to paying deposits. A good deal of ore is being mined on the 1300 level The usual amount of ore is being reduced at the Nevada mill—about 1100 tons a week. The ore averages $20 a ton. There is bullion on hand and at the mill amounting to $48,567.

SILVER HILL —The east drift on the 1600 level is being advanced in a favorable formation.

NEW YORK CON.—The usual prospecting operations are being carried on, principally on the 650, 800 and 900 levels.

ALPHA —The usual exploring work is being done on the 500 and 600 levels.

GOULD & CURRY.—On the 400 level the northwest drift has been extended 18 feet; total length, 153 feet. Formation, soft porphyry. All work on the 625 level for the past week has been confined to repairing west crosscut No. 1.

BEST & BELCHER.—On the 1000 level joint west crosscut No. 1 has been extended 18 feet; total length, 412 feet. Formation, hard porphyry. On the 1200 level west crosscut No. 1 has been extended 15 feet; total length, 51 feet. Formation, clay and soft porphyry.

JUSTICE.—Work is in progress at the usual points, and the ore breasts continue to look well. Are milling about 150 tons a week, the average assays of which are nearly $34.

ALTA.—The ore breasts on the 900 level are still looking and yielding well. The mill is kept running to its full capacity on ore that averages $22 a ton.

SCORPION.—The southwest drift on the 630 level still continues in vein porphyry and clay.

YELLOW JACKET.—The yield of ore is sufficient to keep the Brunswick mill constantly employed. The average of the battery assays is about $20 a ton.

MEXICAN.—West crosscut No. 5, on the 1465 level, is now penetrating softer ground, but porphyry continues to be the prevailing rock.

CHALLENGE CON.—The joint Challenge-Confidence west crosscut No. 2, from the 700 north drift (500 Yellow Jacket level) is out 234 feet, 24 feet having been made during the week, face showing porphyry. The joint Confidence and Challenge west crosscut from the top of the raise on the same level is out 80 feet, 5 feet having been added, the face in porphyry. This crosscut has been stopped for the present, and from its extreme west end a joint Confidence and Challenge south drift has been started, which is in 13 feet, the face showing low-grade quartz.

OPHIR.—The 1300 level winze continues in quartz that carries some metal.

UTAH.—The incline raise on the 72 level is still in a mixture of porphyry and quartz.

Eureka District.

BULLION SHIPMENT.—Eureka *Sentinel* June 28: Last Friday Wells, Fargo & Co. shipped 12 bars of Eureka Con. bullion, valued at $30,300.

ORE SHIPMENTS.—During the past week the Eureka and Palisade railroad shipped 580 tons of ore to the Salt Lake smelters.

Osceola District.

GRAVEL MINING.—Salt Lake *Tribune*, June 28: When asked by a *Tribune* reporter about Osceola, Prof. Maynard gave some interesting particulars of the operations of the Osceola Gravel Co., of which he is manager. The one ditch originally planned and built by the company did not furnish ample water, and it was proposed to construct another ditch and flume to bring water from another and larger stream. Prof. Maynard among his friends in New York raised over $150,000 for the purpose, and during the past year work has been going steadily onward in construction. A canal has been dug and fully flumed 18¼ miles to carry 2500 inches water. Last week water was running through the first 10 miles, to where there is a break to be flumed, and below that water was in three and a half miles more of the canal. By July 1st the fluming will have been completed, and the three hydraulic monitors will be throwing streams on the gravel banks. Two monitors have been running for some time by the old ditch, doing good work. These monitors are among the largest used, part of them having 7½ inch nozzles and the others 8½-inch nozzles. Work is continuous day and night. The company has a 4000-candle power electric light plant to aid in night work. No clean-ups will be made till the end of the season. Some of the boxes required a little changing, and in making the changes a small amount of gold was taken out and shipped. The company has good reasons to feel confident of excellent results in its operations.

Plochs District.

EXAMINING MINES.—Salt Lake *Tribune*, June 28: Prof. Maynard says that Mr. Godbe, the promoter of this enterprise, was considered an enthusiast; that he had known him for a number of years, and what had always been a puzzle about the mines at Ploche was that if so good as represented, it was singular that the companies should shut down as they did when there was so much ore in the mines. Regardless this feature he had, upon investigation, found that the cause of the collapse of mining in Ploche was not because there was no ore, but had come about through the jeal-

ousies and animosities of the companies. The professor went on to say that after spending a week examining the Julia mine from the 800-foot level down to the 1300-foot level, and was not half through, he was ready to say that Mr. Godbe in telling of the property had not told one-tenth. He will return and finish the examination of the Yuba and then make an examination of the other mines there for the purpose of furnishing a full report to the company in New York. He has only passed through the other mines, without examining them critically, but felt fully prepared to make the statement of his surprise and that without a railroad it was impossible to ship ore, but that with a railroad came the possibilities of Pioche being an immense mining camp. One furnace is running at the smelter under the management of Mr. Werner, formerly of the Germania, and Prof. Maynard was sure that it was doing as good work as any furnace in the land. This furnace reduces 50 tons of ore per day.

Tuscarora District.

GRAND PRIZE.—*Times-Review*, June 27: Three hundred and four hundred foot level stopes on the old east and west vein are yielding the usual quantity and quality of concentrating ore. Four hundred foot level winze stopes continue to produce a good grade of concentrating ore, and some high-grade ore, which is being sacked for shipment. Concentrator running steadily; crushed during the past week 500 tons.

NORTH BELLE ISLE.—The stopes above the 300 level are without material change. Left-hand drift from the north gangway, 500-foot level, extended 20 feet; the face is all in vein, showing a great deal of spar.

DEL MONTE.—First level—North gangway has been advanced 16 feet, showing some water and spar. North drift from No. 2 east crosscut advanced 15 feet, face of drift not looking so well; ore is low-grade. Raise from No. 1 east crosscut up 9 feet.

BELLE ISLE.—Upraise from the south drift from North Belle Isle line crosscut, 350-foot level, extended 5 feet, showing a large amount of very high-grade ore.

NORTH COMMONWEALTH.—Third level—Joint raise up 47 feet; progress for the week, 30 feet. Raise in south drift is up 13 feet, following good ore. Line crosscut between Commonwealth and North Commonwealth extended 22 feet. Joint raise on same line up 95 feet, progress 33 feet.

COMMONWEALTH.—Second level—Raise from No. 2 east crosscut has been put up 18 feet, cutting through two feet of good ore, assays from same $220 per ton. The chutes are being put in, and the raise carried up to the first level before drifting on the ore. It will take about five days to complete the work. Work in the stopes progressing favorably; 140 tons of ore hoisted, assay value $23 per ton.

ARIZONA.

ORE AND CONCENTRATES.—Prescott *Journal-Miner*, June 26: A large pack train arrived yesterday with ore and concentrates from the Crowned King mine in the Bradsbaw mountains. The lessee of the Silver Prince and Black Warrior, in the Bradshaw mountains, is taking out rich ore, and has an abundance of it in sight. He expects to start up the Tuscumbia mill shortly on ore from these mines. W. M. Claypool of the Sampling works reports pretty heavy receipts of ore there for the past two months. Miners can get the money for their ore within a few hours after its delivery, which is a great convenience to them. Martin Lewis, the Colorado mining man, who recently purchased a mill from Chas. A. Girdler, has moved it out on the Hassayampa, where it will be used for working ore from mining property recently purchased by the former. Dr. Vickers says that the Congress camp now contains about 400 people, and he claims that it is the most beautiful mining camp on the continent. Three shafts are being sunk on the mine at different points, and a new boist is being put up to continue the main shaft to a greater depth. J. N. Rodenburg says that Jacob Henkle has one of the best opened up mines in the county for the amount of work done. He has between 600 and 800 feet of development, which has been done to the very best advantage to the property. A crosscut run to the ledge cut it at a depth of 1200 to 1500 feet below the surface, making the future working of the mine easy and at the very smallest cost. The ledge shows good ore at every point. There is not a property in the Territory which is more promising for the amount of work done.

BRITISH COLUMBIA.

BONDED FOR FIFTY THOUSAND DOLLARS.—Nelson *Miner*, June 27: The negotiations that have for the past few weeks been carried on between the owners of the Queen Victoria copper claim, Messrs. Brown, Becker and Burr, and several of the Canadian Pacific officials, have at last been concluded satisfactory to all concerned. The claim has been bonded for $50,000 for six months.

TOO EARLY TO PROSPECT SUCCESSFULLY.—A. H. Kidsdale and Bob Wynearls came in on Sunday from a three weeks' prospecting trip down the lake. They report the country difficult to get over, owing to the creeks being high and the timber unburnt. They found several large but barren ledges, countless millions of mosquitoes, plenty of fish, and had bad weather. They have concluded it is a little too early to prospect that section of country, and are camped up at the Narrows.

TEN STAMPS. DROPPING ON POORMAN ORE.—Situated on the right bank of Eagle creek, about a mile from the Kootenay and 300 yards from the Nelson-Sproat trail, the 10-stamp mill on the Poorman mine, owned by the Eagle Creek Gold Mining Co., does not at first sight present a very imposing appearance, but it is very picturesque. The stamps and all the necessary adjuncts for treating the ore are by no means such as belong to early days. They are of the newest and most approved patterns of milling machinery. The power which drives the machinery is obtained from the waters of the creek. About 200 inches of water are flumed a distance of 1000 feet, and this, acting on a Pelton wheel, runs the entire mill with perfect satisfaction. Except the original outlay in flumes, pipes, etc., the cost of the motive power is practically nothing. The ore is obtained from the Poorman mine, about a quarter mile up the hill, and is very rich. Crosscuts have been run so that about 5000 tons of ore are now blocked out ready for stoping. But seven men are at work in the mine at present, as there are about 800 tons of ore on the dump. The regular cleanup has not yet been made; but this district is no longer virgin, as already the first infant bar of bullion has been shipped from this mill. The property is owned by Charles Hussey of Spokane Falls and A. L. Davenport of Portland, who are very well satisfied with the results so far. It is managed by R. B. Huntley.

COLORADO.

READY TO SHIP.—Georgetown *Courier*, June 28: It is said that there is in the neighborhood of 600 tons of ore awaiting shipment at the Commonwealth mine in East Argentine. Hank Beighley has taken the contract to transport the ore, and the way it is being taken out, it will keep four or five teams busy all summer in removing it.

WORK HAS BEEN SUSPENDED for the present at sinking the Centennial shaft, which is down 512 feet and shows a four-foot vein of mineral at the bottom. Work will be confined to running levels. Sinking has been necessarily slow this spring on account of the immense amount of water to contend with.

THE HALL TUNNEL is in between 2200 and 2300 feet. Bad air has prevented rapid work for some time, but this will, in a measure be obviated soon by the extension of the air-box to the breast of the tunnel. Mr. Hall contemplates putting a large drill hole down from the surface some 1500 feet, which will give excellent ventilation for all time. Work had to be suspended at drifting on the veins cut on account of bad air.

IN the lower workings of the Bellevue lode there is a splendid body of ore. The vein is about 18 inches thick, 7 of which is solid. The remainder is streaked throughout. It is claimed that it will mill over 1000 ounces to the ton. In and around that section matters have been very quiet for a long time. Now that this strike has been made a renewal of the once active mining in that locality is assured.

THE MONTE CRISTO.—Aspen *Times*, June 28: Work is being vigorously pushed on the Monte Cristo up Maroon creek. Since the recent discovery, the company is encouraged to believe they will soon be able to put the mine in a paying condition. They are running now to make a connection for air, and when this is completed all of their force will be put to work taking out mineral. Working assays that were brought down yesterday returned about 100 ounces per ton, and Mr. Pelland, who is in charge of the mine, believes that as much as 10 tons per day of this character of mineral can be taken out and shipped.

DAKOTA.

THE BABY SMELTER.—Deadwood *Pioneer*, June 26: Dr. Carpenter was tickled all over yesterday at the excellent manner in which his little pet smelter worked. She was fired up early in the morning and ran cleverly and satisfactorily all day long. Mr. Carpenter is only running about one-half the pressure he did before shutting down several weeks ago, and is elated over his success. Pyritic smelting, he says, is bound to be the proper and paying mode in the future. Some few changes have been made in the machinery since reopening, but were only done for the purpose of making the work more convenient for the workmen.

THE ROASTERS RELINED.—At the reduction works this morning two newly relined roasters will be put in operation. The works has only been running one barrel for the last week, but will after today be able to handle all the ore that comes in. A number of new improvements have been put in this plant recently, enabling them to do very rapid and satisfactory work. Forty-eight hours after the raw material is dumped at the works, it has reached the finishing touch.

TIN.—John Christenson, who is building a number of hoisting-engine houses for the Harney Peak Tin Co., is enthusiastic over the prospects and the amount of tin already developed. The claim over which he is now erecting a hoist has a 130-foot shaft and at the bottom is an eight-foot vein of ore that will average 25 per cent tin.

IDAHO.

THE SMOKY ORES.—Wood River *Times*, June 28: The road to Smoky, which was left in very bad condition by the melting snow, is at last repaired so as to be passable for loaded teams, and hauling will soon begin. Beaton & Rowley's teams have taken a contract to haul in the Carrie Leonard lease ore, and will begin at once. Mr. Jennison has contracted to haul the King of the West ore, and has rigged up an outfit that will haul ten tons per week. He expects to be busy all summer. There is quite a quantity of lease ore at the various other Smoky mines which can now be hauled to market, and which will be coming in from this time on.

MONTANA.

FROM DEWEY'S FLAT.—Butte *Inter-Mountain*, June 28: A representative of the *Inter-Mountain*, who has just returned from a trip to Dewey's Flat, Beaverhead Co., says that camp is in a prosperous condition and the people generally in good spirits. The Jay Hawk M. & M. Co. of Jay Gould is rapidly pushing to completion its ten-stamp mill at that place, and will be ready to commence operations about August. The best machinery obtainable is being placed in this mill, and they fully expect to supply the same from the Pettingale mining property, which they lately purchased. The Lone Pine M. & M. Co., whose mill is also located at this point, is running full force, and pending the completion of the Jay Hawk mill, is crushing the latter's ore.

THE CASTLE DISTRICT.—*Mining Review*, June 28: Great interest is now being manifested in this district, which has long been known as one of the most promising in the State. Nothing but its distance from the railroad has retarded its progress. Now, that it is certain that a railroad will soon be built to Castle, much greater interest is being taken in the district. A number of Colorado miners have secured interests there and are highly pleased with the prospects of the camp. The Cumberland made a strike in the 500-foot level Saturday, and the Princess, owned by Helena parties, is still showing up well. The Yellowstone smelter, which was started Tuesday of last week, as announced in this paper, is producing bullion in considerable quantities, the Yellowstone mine furnishing 50 tons of ore daily, with sufficient ore in sight to continue this daily output for years to come. The increased interest in mining has made business brisk in other lines. It would appear that a mining camp has been started that bids fair to rival Butte in numbers and business.

LOWER CALIFORNIA.

SAN MIGUEL MINES.—*Lower Californian*, June 26: Jos. Williams, superintendent of the San Miguel Mining Co., arrived in town on the 18th inst. from the company's mines 300 miles south of Ensenada. He made the trip on horseback and was 11 days in doing it. The company is working but one mine, which is 60 miles north of Calmalli in a section wonderfully rich in gold and silver, though as Mr. Williams remarked, it has scarcely been touched by the miner's pick owing to the comparative inaccessibility of the region. It is reached most easily by way of Miller's Landing, on the seacoast, whence to the mine it is 24 miles over a good road. The San Miguel Co. have already constructed 40 miles of roads in the vicinity of their property. They have an incline shaft 200 feet deep in the mine and 20 men are at present employed in getting out ore. The ledge is narrow but the ore is rich, and the owners can make a good deal of money out of it. A Bryan mill is on the ground, but it has been idle for some time on account of a lack of necessary machinery, but when that arrives the force of men will be doubled and the output of the mine correspondingly increased. Mr. Williams is enthusiastic regarding the future of San Miguel in a mining way. He believes that it will develop into a very rich section, and that when facilities are established for carrying on the business properly, immense profits will be realized.

A CHANGE IN THE EL PASO COMPANY.—Major George B. Zimpleman is general manager of the El Paso M. Co. no more. If reports now current among mining men are true, he is not even a director in the company. The members of the company in St. Louis have all along been under the impression that the Elsinore mine belonged to the company. At any rate, Major Zimpleman has been working the mine with the company's men and crushing the ore in the company's mill, to the neglect, so it is stated, of the other mines of the corporation. Of course, this was all right so long as the members thought that they were to share in the result of Elsinore's rich yield. But it transpires that at a meeting of the El Paso Co. in St. Louis, Mo., a couple of weeks ago, at which the Major was present, it came to light that the Elsinore was the property of Major Zimpleman, and he surprised his associates by offering to sell it to the company for $50,000, which was only one-half, he said, of what the mine was worth. His proposition was met with exclamations of surprise from the gentlemen present, who believed they already owned the mine, and pointed interrogatories were directed at the Major to explain forwith. He didexplain ,but not to their satisfaction, and the result was that they froze him out and sent Mr. C. J. McLaran out here to take charge of their property.

NEW MEXICO.

A RICH STRIKE.—Silver City *Sentinel*, June 25: John A. Miller made an enormously rich strike in the Pennsylvania mine at Carlisle, last Wednesday. In cutting northward across the ledge, he encountered a large mass of very rich quartz, carrying gold in wire and honey-combed form. On the croppings he discovered a mass of rock running $57 per ton in gold. This mine is in the Carlisle lode, and close by. It was discovered and located the same time as the Carlisle, and was believed by many to be a better mine than the Carlisle was. The strike that Mr. Miller made exceeds in richness anything ever discovered in the Carlisle district. He reports that he has a bond and lease on the Pennsylvania, Center, and Annie mines; some of the owners deny this; also that he has a lease on 20 stamps of the Carlisle mill for six months. The mill is now running.

WEST SIDE CAMP, LONE MOUNTAIN.—Quite a large strike of high-grade ore was made last week in the Good Luck mine, at Westside Camp, Lone Mountain. This is the property of William Beall. The strike improves as development progresses, and promises eventually to assume the proportions of a bonanza. Sweetland & Berry will move into Westside Camp this week, to work the Missouri claim. Bob Redding is working Ed Young's claim, an extension of the Alice. Dan Rose has located a new claim, and christened it the Favorite. He shows up some very good mineral. The Good Luck will ship a carload of ore to Pueblo next week.

OREGON.

AROUND BAKER CITY.—Bedrock *Democrat*, June 26: Mining activity throughout Baker county and in districts tributary to Baker City has not been so manifest thus far this year as usual, the lateness of the spring and the unusual stir in real-estate matters in Baker City combining to detract attention from the hills and gulches wherein lies the great source of wealth of Baker county. But this is at an end and it is plainly apparent that our mines are forging ahead prominently and are taking on their old-time importance. Yesterday the Baisley-Elkhorn, the Robbins-Elkhorn and the Bonanza-Elkhorn mines, 15 miles northwest of the city, were visited by a large party of capitalists. They inspected the workings of the mill plants on the Baisley-Elkhorn and Robbins-Elkhorn mines, examined the ledges and are highly pleased. The Nelson placer mines, west of the city, will yield an immense output this year; so also will the Carpenter and other placers in the same district. At Sanger the C. T. Bradley M. Co. are meeting with great success, and the company's 20-stamp mill is kept in operation constantly, and a monthly output of $20,000 is the result. The mines of Sparta are making a fine showing this year and give assurance that a large amount of capital will be invested in the camp for their development and working. The Dr. Marotte has been sold to Eastern capitalists for $25,000, and the purchasers are making arrangements for a mill plant. The Henderson mines are developing well; the Del Monte group are yielding a large output of ore, and other mines of the camp promise their owners large returns. At Cornucopia the Oregon G. M. Co. are seeing their fondest expectations realized in the wonderful development of the Red Jacket mine, from which is being taken hundreds of tons of high-grade gold ore, which will make that whole section fairly hum with prosperity when the ores are milled and the yield made known to the world. Very recent advices from Cornucopia are to the effect that a second ledge has been cut in the Red Jacket tunnel, the ore from which is extraordinarily rich. The company's 40-stamp mill will soon be in operation. The mines of Mineral City are attracting a great deal of attention, and a large amount of capital is being invested there. The Connor Creek mines continue to send out a large output of bullion to be poured into the coffers of Portland owners. The mines of Burnt river are looking well, and the prospects for the future are flattering. The new reduction process being added to the mill plant of the Eureka and Excelsior Con. G. & S. M. Co., at Cracker Creek, is being constructed as rapidly as possible, and within the next 60 days it may be expected that the camp will take on its former activity and the stockholders in St. Louis begin to realize on their investment. The great La Bellevue mine at Granite, owned by the Cable Bros., is about to be sold to Eastern capitalists for a large sum of money. Work on the 1500-foot tunnel at the Monumental mine progresses with Burleigh drills, and a number of free-gold ledges have been cut, giving favorable signs of future success. The London company, operating the Monumental in the face of a large output of money, are not in the least discouraged and are confident that they will yet realize on their investment. The mines of Greenhorn are attracting great attention, and as fast as the snow disappears mine-owners have resumed development operations. At Robinsonville the mines show favorable and permanent operations will soon be commenced there.

UTAH.

SOLD. — Eureka *Chief*, June 28: We are indebted to B. Christensen for the following information: The Sioux people have purchased the June Bug for $9000; three-fourths interest in the Jessie Knight for $4,00 and one-half interest in the Spy No. 3 for $11,000; $9000 was paid down on the June Bug and Jessie Knight and $1500 on the Spy No. 3. These claims lie near the Sioux group. Shettle & Co., leasers of the Treasure, have secured a lease and bond on the Napoleon, adjoining the Bachman ground. The bond is for $50,000, and some money was paid down. The Napoleon is the property of Condon Bros.

BONDED.—Eureka *Chief*, June 27: R. Thompson, of Colorado, representing Salt Lake capitalists, has secured a working lease and bond on the Mormon Chief and Pride of the Hills, situated about one mile east of Silver City, the property of J. F. Kappes. The bond is for $15,000. A shaft is already sunk 70 feet, and they have some ore, part of which they think will pay. Work has already been commenced, and a whim has been ordered from Denver. R. V. Tone, a miner of long experience in this district, has accepted the position of superintendent.

MCHENRY STRIKE.—Park *Record*, June 28: Contractor Collingwood, under whose direction a force of men are engaged in cleaning out the old McHenry tunnel and drifts, became very much elated last Sunday when a nice vein of ore was uncovered in an old crosscut which had caved in. The property is not yet in shape for active explorations, but as soon as Mr. Collingwood gets through with his job it is presumed that Col. M. Shaughnessy, who has control of the property, will make the McHenry give a good account of itself. The ore lately found assays high in silver and lead, and undoubtedly the find will be developed as soon as practicable.

BEDROCK FLUME AT BINGHAM.—Salt Lake *Tribune*, June 26: Fully fifteen years ago Mr. C. W. Watson began to figure for a bedrock flume in Bingham canyon. Want of means and the death of his partner held him back until about 15 months ago, when he secured the co-operation of Mr. Chandler, and they very soon began the construction of a tunnel. This has been driven over 3000 feet from a point opposite the lead-mill. The tunnel has had the bottom flumed for the purpose of both carrying off the water and saving it, for this enterprise had two objects in view—first to get the gold on the bedrock and secondly to secure pure water for irrigating the lands owned by these gentlemen in the valley, just below the mouth of the canyon. The tunnel has a fall of two inches in 100 feet. Gravel is mined at the upper end and hauled up by machinery through an inclined shaft to be washed. Regarding the quality of the gravel in the portion being worked, it runs from three to four cents per pan. As it is about half boulders, the ground so far opened runs about $1.70 per cubic yard, and is expected to do still better when bedrock is reached. Mining is not being done now because there is too much water. In mining, the gravel will be taken out and the space timbered. This enterprise promises good returns to the fortunate owners. One cleanup was lately made with pretty good returns. Four men are working on the East dump at Bingham, making occasional shipments of ore from the hand jigs. The Winamuck dump (Bingham) has a small force of men operating jigs. A shipment of two cars of concentrates was made last week.

WASHINGTON.

TUNNEL. — Okanogan *Outlook*, June 26: The tunnel on the First Thought is now in 175 feet and progressing at the rate of about five feet a day. H. W. Higley is doing yeoman service in opening up the Lady of the Lake, and the indications are that he will be amply rewarded for his labors. The new hoist is in place and in operation on the Fourth of July, and the work of sinking the double compartment shaft is being vigorously prosecuted. Allan C. Mason has recently had four assays made of Lone Star ore that gave returns of from $43 to $252 per ton, the average being over $100 to the ton. The main shaft on the Lone Star is now down about 350 feet. The ledge at that depth is 6¼ feet wide and plentifully seamed with mineral veins, which are gradually widening out and will soon unite in one solid mass of mineral. Messrs. Lockwood & Taylor returned Thursday from a prospecting trip in the Similikameen district. They discovered some very promising ledges and made one location. They also found placer gold in small quantities, and will return in a few days to prospect the ground more thoroughly.

MECHANICAL PROGRESS.

LUBRICANTS FOR MACHINERY.—A good lubricant is an absolute necessity where friction from bearings is to be overcome, whether in machinery or vehicles. The many kinds in the market invite experiments, which often prove expensive. The cheap axle greases answer where the surfaces are large and where there is ample play, as they are largely constituted of resins which give them a body and hold the cheap greases which form the lubricant; but they are totally unfit for close-fitting bearings. Some fine lubricants are the product of mineral oils, but when purified as they should he they are too expensive for general use. A fine lubricant has been made from cotton-seed oil, but when pure its cost precludes its use in the machine shop; so too castor oil, which when pure is a prime article, is little better than common fat when adulterated, as it too often is. Sperm oil is the best of lubricants for close-fitted surfaces, and where the amount used is small its cost should not serve as a barrier to its use. A good oil which can he prepared by any one with little labor, and which possesses superior qualities as a lubricant for close bearings, can he made of neats-foot oil. Procure perfectly pure neats-foot oil and filter it through a filtering paper placed on a glass funnel. It should be in a room heated to summer heat. Repeat the filtering eight to ten times, the object being, in addition to purifying it, to separate those parts that are likely to oxidize and thicken when the oil is placed in contact with metal. After filtering, the oil should be poured into a tall, thin bottle and stood in a cool place where the light is strong. On being exposed in this way the contents of the bottle will separate; the heavy portion, which will have a granular appearance, will settle to the bottom, leaving on the top a thin limpid oil. Pour this off carefully; if any of the heavy particles have been mixed with the light oil, filter it and then mix with equal weight of benzoline, and it is ready for use. This oil will not thicken and will wear longer than any of the lubricants on the market. It is also very much cheaper than any except the common greases.—*Exchange.*

MANGANESE STEEL.—When Hadfield's manganese-steel was offered to the public it was recognized that, in spite of its remarkable combination of hardness, strength and ductility, a combination in which it excelled all known substances, the difficulty of machining it would be a serious obstacle to its introduction. Partly by special means of grinding with emery, partly by casting in such a way that machining is unnecessary, and partly by other expedients, this obstacle is gradually overcome and manganese-steel is steadily forcing its way into wider and wider use. It is, for instance, used extensively for mine-car wheels and axles, a single establishment having taken over 40,000 wheels and 20,000 axles. It has been found very valuable for the rivets of safes. These rivets are countersunk, so that, if they are to be removed, they must either be drilled out or punched out. In some recent trials by an experienced safe-maker it was found quite impracticable to drill these rivets, when of manganese-steel, even with a powerful steam drill working in the way found most effective for hard-steel rivets. He then tried to punch them with a set and a 20 pound hammer, but in vain. The iron which the rivet held was then nicked and broken, releasing the rivet, which seemed quite uninjured. Other characteristic uses are for dredger-pins and stamp-shoes and dies. In some late trials manganese-steel dredger-pins outlasted four sets of forged carbon-steel pins, and still remained in use; and manganese-steel shoes and dies, in crushing Cornish tin ore, are reported to have lasted from 26 to 59 per cent longer than the maximum life of the best chilled cast-iron, and to have crushed from 33 to 85 per cent more ore.—*Engineering and Mining Journal.*

SHAFTING AND PULLEYS.—The general progress which mechanical engineering has made during the last quarter of a century, remarks London *Engineering*, has affected not only the more imposing class of works, such as bridges, steamships, etc., but also almost every detail of the workshop and factory. Take, for instance, the item of shafting and accessories. Within the period mentioned, shafting, instead of being made of wrought iron, has come to be made of steel in all the newer and higher class factories. The bearings, instead of being rigid, are now usually of the type known as swivel bearings. These not only accommodate themselves to any irregularity in the movement of the shaft, but they are longer than they used to be made, and therefore are more enduring, and they are furnished at the ends with cups to avoid the annoyance of the continual dropping of dirty oil. If lubricated with needle lubricators they require no attention except at long intervals, and there is no liability to run dry. Pulleys, instead of being solid, are now always in halves, so that they can be slacked and shifted, or removed altogether in a very short space of time. The mere screwing together of the two halves is sufficient to fix a pulley to the shaft without the necessity for keys, as was formerly the case, and which so often threw them out of true. As regards very large pulleys, the construction of these of wrought iron or steel by building them up, as it were, has become a large and important business; even fortunes have been made out of the manufacture of them. The first person who advocated and made large wrought-iron pulleys was the late Joseph Rodgers of Leeds; and large quantities of them are still made by his late partners.

MARVELOUS ADVANCEMENT OF THE WORLD'S IRON INTEREST.—Within the last quarter of a century the iron interests of the civilized world have made more progress than any other one interest known to commerce. Formerly all the iron used in the United States was imported from foreign shores, either in pig iron as ballast or in the manufactured article, and so continued until within a recent period; but now the tide has turned. Not only do we supply ourselves, but we are shipping iron to our European neighbors across the big waters! What, may he asked, is the cause for all this vast change? Many things have entered into the list of cause and effect, among which of the greatest moment is the increased price of production in Europe and the indomitable enterprise of our American citizens who have opened and are working hitherto unknown mines with a result heretofore unknown in the iron interests of the world. When Pennsylvania, Ohio, Indiana, Missouri and other States first attempted to utilize their ores, they found they could not compete with Europe on account of her cheap labor and the high prices of labor on this side of the world; consequently the tariff had to be raised in order to give American producers an even chance with the Old World. Now another new era has set in.

AMERICAN FIRE ARMS MADE IN EUROPE.—When the importers of fire-arms came before the Congressional Committee on Ways and Means to ask for a moderate duty on this class of goods, Mr. Walker, member of Congress from Massachusetts, showed that he knew something about arms himself by asserting that the devices of modern guns are American; the most improved modern machinery is American; foreigners have been to this country, copied our models and secured our machinery, and are making the guns now imported to this country from our patterns and machinery, and they are only able to do this by the fact that labor is cheaper in Europe. He added that the average wages paid to gunmakers in Belgium is 50 cents a day, against $2.50 and $3 25 in this country, and presented official statistics showing that there were 117,000 guns imported into the United States last year by reason of this cheap European labor, while only 25,000 were manufactured in this country. No attempt was made to controvert this view of the case.

A MARKET FOR OUR AGRICULTURAL IMPLEMENTS.—Spain presents an excellent market for the introduction of American farm implements, so says our Consul at Cadiz. Referring to the statistics of exports from the United States to Spain for the year ending June 30, 1889, we observe that the value of agricultural implements exported amounted to only $7316, of which about one-half applied to mowers and reapers. This was but a fraction of the total exports to all countries. This does not represent the extent to which American implements are used in Spain, for it appears that many of them are obtained through German, French and English sources, which present more favorable conditions of purchase, in which the system of long credits acts an important part in trade.

THE IRON AND STEEL INSTITUTE OF GREAT BRITAIN will visit the United States next fall. This representative body will probably send over 400 of its members. They will he joined by more than 100 members of the corresponding German society, and will on arrival he taken in charge by the American engineers, and everything that can he done to make their visit a pleasant and memorable one may be anticipated. It is proposed to take the visitors all over the United States and let them see for themselves the giant strides which America is taking in the iron industry. When the visit occurs, much interest will be felt in the reception and proceedings. At present nothing beyond the announcement of the trip is in order.

IMPROVED PUMP VALVES.—In some pumping stations in Germany, pump valves are made tight by grooving the valve seats and inserting rubber cord in the grooves. The cord is compressed when the valves seat themselves, and effectively guards against leakage; in addition to this it prevents the shocks ordinarily produced by rapid closing, and prolongs the life of the seats. The importance of this will be readily appreciated by those familiar with the working of pumps under high-water pressures. When worn, the rubber cord is easily replaced.

THE LIFE OF A STEAM PLANT has lately come up for discussion. For depreciation of machinery 10 per cent is usually allowed by manufacturers, but it is a question if the steam plant is so short-lived. Twelve years is usually given as the life of an ordinary boiler, yet there are many boilers now in use that have been run for over 20 years. The whole question depends, then, upon conditions of use and care, as much, if not more, than the construction, providing, of course, this is not radically defective.

BLACK JAPAN FOR METALS.—Two ounces of asphaltum and five of umber, mixed with a quart of linseed oil, is said to produce a first-class black japan for metals.

SCIENTIFIC PROGRESS.

SILK DIRECTLY FROM MULBERRY LEAVES.—According to a report recently presented to the Paris Academy of Sciences by Emile Blanchard, a professor of chemistry, there is a hopeful prospect that it will be quite possible, at a not remote epoch, to manufacture silk directly from the leaves of the mulberry tree, without the intervention of the cocoon. Numerous experiments have already been made in this direction, but nothing practical has resulted. M. Blanchard, however, is confident in the experiments made by himself. He is convinced, for instance, that the constituent materials of silk are to be found in the mulberry leaf, upon which the silkworm feeds. By dyeing some of the leaves on which a worm fed and then after awhile opening the body of the chrysalis, he found that nothing had passed through the digestive organs and into the blood except the elements necessary for the production of silk. Other matters had been excluded by certain glands of the worm which had acted as a membrane. M. Blanchard confesses, however, that the silk which he produced by experiments with mulberry leaves was inferior in richness, and particularly in gloss, to that furnished by the cocoons. This resulted from the fact that, as the silk goes through two processes in the glands of the worm, he had only the time and the means to study the first—that in which the silk is evolved in its primary state. He believes, however, that it will he possible eventually to produce, by chemical means, the gloss or varnish which is the result of the second stage through which the silk passes in the body of the insect which produces it.

GOLDEN MAGNESIUM.—M. N. Varren finds that when the metal magnesium is heated in a current of ammonia thoroughly dry, and keeping the temperature below a red heat, it combines with the gas without changing much in appearance, though its chemical properties are much modified; for instance, it will not melt below a bright red heat, and burns, when red hot, with violent decrepitations or small explosions. If the current of ammonia is continued, and the metal in this form heated to bright redness, it is gradually converted into an orange-yellow substance which is permanent. This new product dissolves in acids, and the solution contains ammonia. When fragments of magnesium which have been kept at a dull red heat for some time come in contact with gaseous ammonia, it often happens that their surface becomes dark yellow and shines like gold. The exact nature of this golden magnesium has not yet been made out.

ORIGIN OF FLAVOR IN BUTTER.—Several Danish chemists and analysts have been endeavoring to find out the origin of flavor in butter, which, according to some, is held to be caused by bacteria—whether the flavor be that of turnips, oily, fishy, bitter or tallowy. Prof. Storch has found large numbers of bacteria of a particular variety in oily butters, though he was not able to produce oily butters by the introduction of these bacteria into cream. In other cases he found bacteria which did not differ materially from the normal acid-producing bacteria, which when present in large quantities in cream, produced butter of a tallowy flavor. Similar results were obtained by Prof. Jensen; while Prof. Fjard found that butter from a farm where turnips were not used for the cows had a turnipy flavor, and it is believed by the investigators that this flavor is derived from the presence of a certain kind of bacteria.

IS COLOR BLINDNESS DUE TO A DEFECT OF THE BRAIN?—Prof. Ramsey believes that the particular defect giving rise to color blindness lies not in the eye itself, but in the brain. Certain persons, he points out, are incapable of judging which of two musical tones is the higher, even when they are more than an octave apart. Yet, as such persons hear either tone perfectly, the defect is not one of deafness. He accordingly argues that in such persons the brain is at fault, and thence proceeds to the assumption that it may be equally true that the inability to perceive certain colors is not due to a defect in the instrument of sight, the eye, but to the power of interpreting the impressions conveyed to the brain by the optic nerve. If this is the case, the problem is no longer a physical one. It falls among those with which the mental physiologist has to deal.

MINERAL MATTERS IN COTTON.—Dr. Bowman states that the mineral matters in cotton amount to from 1 to 1.5 per cent of the weight of the fiber. Carbonate of potassium is the chief constituent. There are other salts and phosphates of magnesia and lime, and an amount of peroxide of iron, varying from three to six per cent of the quantity of inorganic matter. The iron is highest in Egyptian cotton. Alumina is also reported as constituting 7.9 per cent in rough Peruvian cotton. This mineral matter is regarded as an integral part of the fiber. If, as Dr. Bowman says, "It is impossible by any means at our command to separate or remove these mineral constituents from the fiber," dyers and printers would be in difficulties; but surely they are nearly all removed in ordinary bleaching operations.—*Textile Recorder, Eng.*

A CURIOUS STONE.—A Finland paper mentions a curious stone in the northern part of that country, which serves the people instead of a barometer. This stone, which they call "Ilmakiur," turns black, or blackish-gray, when foul weather is approaching; fine weather has the effect of turning it almost white.

A SCIENCE OF MYTHOLOGY.—It is believed that the myths and folk-lore of different peoples, when properly studied, will add a valuable chapter to the history of the human mind. "The time is coming," said Jeremiah Curtin, "when mythology may become a science, if scholars will work for that end, but mythology is far from being a science yet. There are many theories and loose statements current about mythology—'disease of language,' 'sun myths,' 'serpent myths,' etc.—but there is no science in all this. It is fancy, guesswork, efforts of men dealing with insufficient and unsatisfactory materials, collected, in many cases, by incompetent hands or by persons who tamper with materials for the purpose of improving them, or fitting them to some theory." The things needed, this author avers, are facts, and facts in mythology are well-preserved myths.

THE CHANGES CAUSED BY DUST CARRIED BY THE WIND.—Water is not the only physical agent concerned in carrying the earth's solid materials from place to place, modern investigations proving that the dust carried by the wind produces astonishing changes in the configuration of the land. The thick deposits covering ancient ruins are now believed to have been largely brought by the air. A French geographer, M. Violet d'Aouest, after referring to Richthofen's description of a vast aerial soil-formation in China, mentions having seen on the flanks of high mountains in Mexico clay strata not deposited by the waters nor by the decomposition of the rocks, but produced by the dust raised from the plains by the winds and left on the hills. These deposits vary from 100 to 300 feet in thickness, growing finer with increase in hight, and ceasing at the limit of vegetation.

IS PURELY SCIENTIFIC TRAINING DESIRABLE? Men of purely scientific training are of less assistance in practical affairs than their education would suggest. The man of science has little faith in new methods or new inventions. He is seldom an originator. His knowledge is that of tradition. He frequently scouts at new ideas as impracticable, because they are not recognized in the books. The inventor seldom travels in the same road with the scientist. The inventor needs to leave the beaten path and press on to the unexplored forest of possibilities. He is often handicapped if he endeavors to conform to rules already laid down by pure science. Few college-bred men have proved inventors. Original thought, bold action, patient persistence, knowledge of nature's laws, are prime factors in the successful career of the inventor.

A CURIOUS PHENOMENON.—When the sun sets in the sea, a curious appearance, as of a bluish-green flame, is sometimes observed. This has been thought to be due to the light passing through the crests of waves. But Prof. Schncke considers this view disproved by such an observation as that recently made by Prof. Lange, at a watering-place on the Baltic. Shortly before sunset the disk was divided in two by a thin strip of cloud, and just as the upper part disappeared under the cloud, the blue flame was observed. Thus the cause appears to be in the air, not in the sea. It is a case of atmospheric refraction, and as a planet, seen near the horizon with a good telescope, appears drawn out into a spectrum, with the more refracted blue-violet end higher than the red, so the last visible part of the sun furnishes the blue-violet end of a spectrum.

HOW TO FORETELL A STORM.—When a storm is advancing, the wind blows to meet it. Thus a wind blowing from the east or southeast indicates the approach of a storm from the west. When the storm center has passed, however, the wind changes and follows the storm. If a person has a good barometer and a wind gauge, he can tell pretty correctly when a storm is coming. Without the instruments the clouds may he watched, and when seen to he moving rapidly from the southeast, and there are indications of the presence of moisture in the air, a storm is not far away.

ELECTRIC RAILWAYS.—As illustrating the progress of electric railways, it may be stated that there are about 130 towns in the United States with one or more electric railways in operation, construction, or under contract, and that these roads comprise about 1500 miles of track, equipped with about 1700 motor cars, requiring 3000 motors of an aggregate capacity of 45,000-horse power, and steam and electrical generators of 25,000 horse power. The roads in operation are making about 100,000 miles per day, and within three months the mileage will be doubled.

A NEW ZINC FOR ELECTRICAL BATTERIES.—The Electrical Improvement Syndicate of Boston control the output of a new zinc, the important feature of which is its amalgamation, the mercury being incorporated into one homogeneous mass, making its life three times as long as ordinary amalgamated zinc. The internal resistance is very much less, while the electro-motive force is increased. The zinc will be made in all sizes and forms, and can be applied to any battery.

GOOD HEALTH.

The Liver.

The liver is the largest gland of the body. It carries on several separate and distinct lines of work. We are best acquainted with its work of making bile, which is largely, if not entirely, made up of waste elements taken from the blood. Bile is a golden-yellowish fluid, but when vomited from the stomach it is green, and many people suppose that this is its natural color. The change is due to the action of the gastric juice.

It is an excretory and digestive fluid, converting fats which are not acted upon in the stomach, but in the small intestine, into an emulsion. Bile also acts upon the mucous surfaces, stimulating the absorption of food after it is digested.

The digestive fluid of the stomach is acid, the bile is alkaline, and the two being poured into the small intestine simultaneously with the food, prevent an irritating action of the gastric juice. Pure gastric juice is so strong an acid that it will irritate the hand if it is placed upon it. Were not the stomach protected in a peculiar manner, it would itself be digested with the food, as often happens in cases of sudden death after a person has just eaten a hearty meal.

Bile stimulates peristaltic action, by which means the food is moved along through the entire length of the intestines. It is an antiseptic, and preserves the food from fermentation and decay in its slow progress through the 25 feet of alimentary canal. This is one of its most important uses. With the food is always taken a quantity of germs, and they would surely induce fermentation but for this preventive agent. About 14 hours are required for the complete process of digestion from the time food enters the stomach until it is entirely absorbed. If a single one of these several offices be absent or interfered with, it seriously affects the health of the individual.

The liver itself is a digestive agent. All the digested food, with the exception of a small portion of the fat, is absorbed and carried by the portal vein to the liver. The heart pumps blood direct into the general circulation, but all of it which goes to the stomach, spleen and other abdominal viscera is carried to the liver before it is allowed to go into the general circulation. Thus the liver acts as a filter for the blood received through the portal circulation and completes the work of digestion. The stomach is only the ante-chamber where the process of digestion is commenced.

There are 25 feet of intestines, and the work of these upon the food is vastly more important than that of the stomach. When the stomach and intestines have done all that they can do to the food, its nourishment is expended and it is carried off as waste matter by the kidneys. The liver acts upon all its elements, which no other organ does. Starch constitutes one-half to two-thirds of all our food. When we take it into the month, the saliva begins to change it into sugar. It furnishes heat for the body and muscular and brain force, hence we need a large amount of it.

In the process of digestion, a large amount of sugar is manufactured. If all this were poured at once into the circulation, it would thicken the blood and render it so sluggish that the blood corpuscles would all be destroyed, and it would have to be hurried out of the system to save the person's life; so the liver goes immediately to work to change the sugar back into liver starch, and stores it up in its tissues. Then it begins slowly to change the starch back into sugar again, and doles it out for use as needed for force, heat, etc.

The liver is also a sort of rendering establishment. It takes what would otherwise be offensive and dangerous elements and utilizes them, just as the rendering establishments of large cities take the dead animals and offensive garbage and make them of value. The liver takes all the broken down tissues, the millions of dead blood corpuscles, works them over and changes them into material of which corpuscles can be made. The coloring matter found in these corpuscles is worked over into material which furnishes coloring matter for the eyes and hair, as well as furnishing color to the bile. Nature shows wonderful economy in thus taking old, worn-out material and converting it into such a variety of new uses.

The bile containing waste alkaline substances, also makes a little soap out of the fat that aids in preparing the rest of the fatty material for absorption.—*Hall's Journal of Health.*

THEISM, THE NEW NERVOUS DISEASE.—Attention has recently been drawn to a new nervous disorder said to be especially prevalent in England and America. It is called "theism," or tea-drinker's disease, and is said to exist in three stages—the acute, subacute and chronic. At first the symptoms are congestion of the cephalic vessels, cerebral excitement, and animation of the face. These physiological effects being constantly provoked, give rise, after awhile, to reaction marked by mental and bodily depression. The tea-drinker becomes impressionable and nervous, pale, subject to cardiac troubles, and seeks relief from these symptoms in a further indulgence in the favorite beverage, which for a time restores to a sense of well-being. These symptoms characterize the first two stages. In chronic cases, theism is characterized by a grave alteration of the functions of the heart, and of the vaso-motors, and by a disturbance of nutrition. The patient becomes subject to hallucinations, "nightmares" and nervous trembling. With those who take plenty of exercise, and habitual consumption often may be indulged in with impunity, but with women and young people who follow sedentary occupations this is not the case. The best treatment for theism is said to be indulgence in free exercise, such as walking and open-air life.—*Journal of the American Medical Association.*

USEFUL INFORMATION.

TO OBTAIN A LIGHT INSTANTLY WITHOUT THE USE OF MATCHES, and without the danger of setting things on fire, is an easy matter. Take an oblong vial of the clearest of glass, put into it a piece of phosphorus about the size of a pea, upon this pour some pure olive oil heated to the boiling-point, the bottle to be filled about one-third full; then cork tightly. To use the light, remove the cork, allow the air to enter, and then recork. The whole empty space in the bottle will then become luminous, and the light obtained will be a good one. As soon as the light becomes dim, its power can be increased by opening the bottle and allowing a fresh supply of air to enter. In very cold weather it is sometimes necessary to heat the vial between the hands to increase the fluidity of the oil, and one bottle will last all winter. This ingenious contrivance may be carried in the pocket, and is used by the watchmen of Paris in all magazines where explosive or inflammable materials are stored.

ECONOMY IN THE USE OF COAL.—In burning coal in a grate it is very important, in the matter of economy, to place carefully the half-burnt lumps to the front of the grate, and then putting the fresh coal at the back, whenever the fire is "made up," taking care not (as most servants do) to put any coal on any flame there may happen to be, but at the back of it, as by that means you maintain a cheerful fire, benefit by the rays of the heat given off from the flame and live coals while the fresh is lighting, prevent in some cases your chimney smoking, and make some of the smoke from the fresh coal burn (a considerable saving), and which would otherwise cause your chimney to require sweeping oftener.

TO DETECT ADULTERATION IN WHITE LEAD.—If any one has a suspicion that white lead is adulterated, buy a pound or two of the substance, place it in a ladle and set it on fire. After it is completely burned there will be a quantity of metallic lead in the bottom of the ladle. After the ladle is washed and dried, it may be weighed; should it weigh exactly as much as the white lead before being burned, then the white lead is pure. Should a less weight of lead be found, there is an adulteration, the per cent of which may be obtained by dividing the loss of weight by the weight of the white lead before being burned.

STEAM VS. COMPRESSED AIR IN GUNNERY.—The substitution of steam for compressed air in a gun intended to throw shells containing dynamite or other high explosives is proposed in France, the advantages claimed being the furnishing of power direct from the boiler, without the use of air-compressing machinery. The pressures usually carried in steam boilers would not be sufficient for this purpose, but boilers are promised of a special type, which will supply steam at a pressure of from 600 to 800 pounds, and which will, at the same time, be safe and easily handled.

AN INVENTION, in the sense of the patent law, means the finding out, the contriving, the creating of something which did not exist and was not known before, and which can be made useful and advantageous in the pursuits of life, or which can add to the enjoyment of mankind. In other words, the thing patented must be new and be useful to an appreciable extent, though the measure of that usefulness is not material. Any degree of utility appreciable by a jury is sufficient, upon the question of utility, to sustain a patent.

THE RELATIVE VALUE OF GOLD AND SILVER is now a matter of growing interest to the commercial world. With silver worth 103⅛ per ounce, gold is worth 20 times as much as silver. The point where the free coinage of silver is to be compulsory by the proposed bill is when its value reaches one-sixteenth of the value of gold. This will require a further advance of only .25⅞, which will bring the price of silver up to 1.29⅜, or one-sixteenth of the value of gold.

COLOR AND NUMBER IN HAIR.—A scientific German has taken four heads of hair of equal weight and then proceeded to count the individual hairs. One was of the red variety, and was found to contain 90,000 hairs. Next comes the black with 103,000 hairs to its credit. The brown had 109,000, and the blonde 140,000.

CAMPHOR, which lately doubled in price, owing to the demand for it to make smokeless powder, has now receded to near its normal value in consequence of the fact that the European governments have abandoned its use in that manufacture.

ELECTRICITY.

Electric Heating.

The enormous heating-power of the electric current, which the introduction of the dynamo demonstrated, led to the early suggestion that the current, besides its utilization for light and power, might be employed as a heating agent. Without entering into the possible economy of such an employment of the electric current as compared with the other methods now in use, it is beyond question that, as a heating agent pure and simple, there is none which is more perfectly adapted to the purpose than the electric current, supplied, we will say, from a central station. It furnishes heat without any of the accompaniments which are invariably the adjuncts of other heating methods.

An ingenious apparatus for this purpose, adapted especially for employment in connection with the alternating current, has been devised in which the secondary of an induction coil is made in such a form as to generate a maximum of current to produce the desired heating. As the inventor naively suggests, the heating of the iron core, so objectionable a feature in the usual alternating current apparatus, presents no obstacle to the successful operation of the electric heater, and might indeed be classed as one of its advantages.

The promises of the use of electricity in this direction are excellent, and many ingenious electricians are working at the problem. Already a system has been devised for heating railroad trains, and while the principle involved is not altogether a newly discovered one, the present application is far more practicable than when it was first employed. And why should we not obtain heat as well as power and light from the current, since that, quite as well as the two last mentioned, is one of its properties?

At the forthcoming electrical exhibition in St. Louis it is intended to illustrate very fully the remarkable progress which has been made in the application of electricity for heating purposes. Among other devices, there will be ordinary looking flat-irons to which flexible cord is attached, and to which the heat can be instantly transmitted by a slight pressure. Soldering irons with similar connections can be heated without any waste of time, and the usual fire-pot can be dispensed with. Tea-kettles, cooking dishes, tin pans and every description of culinary articles can in the same way be placed anywhere, and their contents boiled or baked in the time ordinarily taken in lighting a fire. Portable radiators will also be on exhibition, which can be carried with the greatest ease from one room to another, and which, when connected, will warm the apartment. Supplementing this exhibit will be a number of improved thermostats or temperature controllers, by which the temperature of a room can be absolutely regulated.

Electricity Versus Steam.

The *American Machinist*, in a recent article, thus discusses the probability of electricity ever superseding steam upon railroads:

By the use of an electric motor the reciprocating parts of the present locomotive can be avoided, and none but rotating parts employed; this will make practically perfect balancing possible, and together with the fact that an electric motor for a given train and speed can be lighter than the present locomotive, would seem to give considerable advantage to electricity, while the difference in economy between the best locomotives and the best stationary engines of the compound condensing type gives a margin of about 50 per cent for loss of energy by conversion into electricity, and back again into motive-power.

Whenever it is shown that the loss by this conversion and reconversion is less than 50 per cent, under ordinary every-day working conditions, the question of economy will be in a fair way of settlement, though there will still be the question of the comparative cost of repairs and interest on money invested in motive-power machinery, and this is a point about which there is little absolute knowledge as yet.

But there is some doubt as to whether the system of having power installations along a line at intervals, generating electricity to be taken by the motors from a conductor placed along the track, would prove practically applicable to railroads, especially on very busy and crowded sections; but it is safe to say that the science of electricity is not yet sufficiently developed to enable any one to foretell in what way it will supersede present arrangements, and it is well for those who attack the problem to remember the maxim, "Never despise your enemy," for the locomotive is quite an efficient machine, all things considered, and we are by no means sure that it has reached the limit of its development in regard to either speed or economy.

ELECTRIC MOTORS ON GATLING GUNS.—Should there ever be another war between two of the foremost nations, electricity would certainly perform a very important part in the operations. The latest conception in this line is the firing of Gatling guns by electric-motor power. The Crocker-Wheeler Motor Co. now have in their new shop a Colt Gatling gun, to which they propose to attach one of their motors, by the operation of which it will be possible to fire 1000 shots per minute. The heating of the barrels will be the only limitation to rapidity of firing. By the hand method it is possible to discharge 500 shots per minute. One thousand shots a minute would soon annihilate an army.

ENGINEERING NOTES.

A FIRST PRINCIPLE OF BRIDGE-BUILDING.—If one plank would hold up 100 pounds on the center, then two planks placed side by side would hold up 200 pounds; while, placing the planks one on top of the other, and nailing them firmly together, they would hold up 400 pounds. In this way we see that, in order to increase the strength of the bridge or beam faster than we increase the amount of the material, the increased amount of material should go into the depth of a beam and not into the width of it. This is one of the first principles in the resistance of material, that the strength of a beam varies directly as the width—that is, if we make it twice as wide, it will hold twice as much; and that the strength varies as the square of the depth—that is, if we make it twice as deep, it will hold up four times as much. If we make it three times as deep, it will hold up nine times as much of a load. So that it can be readily understood that, in order to increase the strength of the bridge or beam without increasing the material in the same proportion, the increased amount of material should be put into the depth and not into the width.

TREE-FELLING BY DYNAMITE.—Some interesting experiments were made the other day in the vicinity of Copenhagen, with tree-felling for military purposes, by dynamite. The object was to ascertain the saving in time and labor effected by this method and the results were exceedingly satisfactory, far more so than is understood to have been the case elsewhere. Trees of as much as three feet in diameter were brought down in some 20 to 25 minutes, whereas the time occupied by ordinary felling would have been 10 times as much.—*Engineering, London.*

UTILIZING RUNNING STREAMS.—The utilization of running streams is the object of many recent devices, among which may be mentioned that of M. Tayn, a Russian engineer. His apparatus consists of an endless cable, carrying a series of canvas cones, which open and shut like an umbrella. The cable passes over a double drum on board a pontoon, and at the other end over a pulley suspended from a buoy. On the lower part of the rope the cones are opened and forced forward by the current of water, thus setting in motion a shaft or drum.

ENGINEERING DANGERS.—The great monsters of engineering skill and genius call for the sacrifice of a great deal of life and limb in their construction. The greater the engineering feat the more extensive is the loss of life. In the construction of the Eiffel tower, for instance, 26 lives were lost according to the official returns of the French Government, while on the great Forth bridge of Scotland a list of 40 lives lost has been published.

A CANADIAN RAILWAY TO ALASKA.—The project for a Canadian railway to Alaska is about taking definite shape. Application will be made to Parliament at the next session for the passage of an Act incorporating a company to build such a road. If the Government at Washington is not more careful of our national interests, the Canadians will get away with the bulk of our northern carrying trade.

ELEVATED RAILROADS IN BOSTON.—The Street Railway Committee of the Massachusetts Legislature has reported to the Senate a bill granting a charter to the West End Street Railway Co. to construct, equip, maintain and operate a system of elevated railways in Boston. The document provides security and restrictions for all the interests of private parties which may be affected.

DR. PIERCE is doing nothing with the immense water-power he controls at the outlet of the Big Bend mining tunnel. The English syndicate that lately bought the Cape claim intends to make good use of its water. Operations at the Golden Gate mine are being pushed, and it is hoped to have the river current diverted before many weeks, when mining will begin.

AN IMMENSE BRIDGE SPAN.—One of the greatest as well as most interesting triumphs of modern engineering is the cantilever bridge across the Firth of Forth. One of the cantilevers of this structure, set up on end, would be nearly as tall as the famous Eiffel tower, and whereas the latter weighs 7500 tons, the Forth bridge has required over 50,000 tons of steel.

THE Oakland & Berkeley Rapid Transit Company has decided to propel its cars by the Sprague system. It is expected to have the road in operation by November 1st. Cars will start to ply between Oakland and Berkeley every ten minutes.

COMPOUND LOCOMOTIVES, burning petroleum, are now being introduced upon Russian railroads.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Hinkle's Improved Ore Feeder; James' Single Track Locomotive; Bowers' Roller Quartz-Mill; The Bowers' Improved Crushing Rolls, 1. New Almaden Quicksilver Mine, 9

EDITORIALS.—Hinkle's Ore Feeder; A Single Track Locomotive, 1. Passing Events; Deep Prospecting for Gold; Gold Mining in Victoria; The Mechanics' Fair; California Asbestos; Underground Temperature, 8. Bowers' Roller Quartz-Mill; The New Almaden Quicksilver Mine, 9.

CORRESPONDENCE.—The Mines of El Dorado County; Mines and Prospects Around Shoup, Idaho, 2. Ophir District, Placer County; The Gold Belt of Northern California, 3.

MECHANICAL PROGRESS.—Lubricants for Machinery; Manganese Steel; Shafting and Pulleys; Marvelous Advancement of the World's Iron Interest; American Fire Arms Made in Europe; A Market for Our Agricultural Implements; Miscellaneous, 6.

SCIENTIFIC PROGRESS.—Silk Directly from Mulberry Leaves; Golden Magnesium; Origin of Flavor in Butter; Is Color Blindness Due to a Defect of the Brain; Mineral Matters in Cotton; A Curious Stone; A Science of Mythology; The Changes Caused by Dust Carried by the Winds; Is Purely Scientific Training Desirable; A Curious Phenomenon; How to Foretell a Storm; Electric Railways; A New Zinc for Electrical Batteries, 6.

GOOD HEALTH.—The Liver; Theism, the New Nervous Disease, 7.

USEFUL INFORMATION.—To Obtain a Light Instantly Without the Use of Matches; Economy in the Use of Gas; To Detect Adulteration in White Lead; Steam vs. Compressed Air in Gunnery; Color and Number in Hair, 7.

ELECTRICITY.—Electric Heating; Electricity Versus Steam; Electric Motors on Gatling Guns, 7.

ENGINEERING NOTES.—A First Principle of Bridge-Building; Tree-Felling by Dynamite; Utilizing Running Streams; Engineering Dangers; A Canadian Railway to Alaska; Elevated Railroads in Boston; An Immense Bridge Span, 7.

MINING SUMMARY—From the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Wyoming, 4-5.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 12

MARKET REPORTS.—Local Markets, Eastern Metal Markets, 12.

Business Announcements.

[NEW THIS ISSUE.]

Water Motors, Etc.—Tuerk Hydraulic Power Co., Chicago.
Dividend Notice—Pacific Borax, Salt and Soda Co.
Mining Foreman Wanted—"Quicksilver," Calistoga.
Assessment Notice—Gray Eagle Mining Co.

Passing Events.

There is little or no change in the situation as regards the molder's strike. Some few more men have left the shops, but others are on the way to take their places.

Elsewhere in the PRESS will be found a brief description of the first electrical plant to work a quartz mill in California. More attention is being turned to the application of electrical power to mining, and a few practical examples of this kind will do much toward its more general use.

The annual public demonstration of patriotism occurs this week on the Fourth of July holiday. Another patriotic theme is the birth of more States into the national family. Idaho and Wyoming are the latest arrivals—twins of 1890 following the quartet of 1889. It is expected that President Harrison will sign the bills for the admission of these two States on the National holiday.

On Wednesday the silver conferrence met and discussed the difference between the Senate and House on the silver question. At this writing it is difficult to form a correct opinion regarding what the outcome of the conferrence will be, but the prevailing opinion is that an agreement will be arrived at, and the bill as agreed upon be reported back to the two branches of Congress, which will lose very little time in passing it.

Deep Prospecting for Gold.

As stated elsewhere in the PRESS, there are some very deep gold mines in the Colony of Victoria, the deepest of which is 2640 feet. This is the Lansell 180 mine, Sandhurst, and rather a curious experiment is being tried there. The owner offered to place this deep shaft at the disposal of the Government Mine Department, for the purpose of having the ground tested by diamond drill beyond 2640 feet depth, he furnishing the power—compressed air—for the drill. The Department of Mines runs a number of drills for just such purposes. They have 14 diamond drills prospecting for gold and coal in different parts of the colony.

The Mines Department accepted the offer, and at the suggestion of the underground manager at Sandhurst, who has a thorough knowledge of the country, and was instructed to report on the best portion for boring, they began a *horizontal* bore at the 1300-foot level. It is thought that some one of the well known ledges would probably be cut by this horizontal bore. When this is completed it is the intention of the Department to commence boring vertically at the bottom of the shaft, 2600 feet, for a further distance of 1000 feet.

These operations will not only be of great scientific interest, but will also afford information as to the character of the country penetrated, which must be of great value to the mining community in general, and more especially so in Sandhurst district, where deep mining is carried on to a greater extent than elsewhere. The mine is well situated for such a trial, so far as depth and nature of workings is concerned.

It is to be remembered that this undertaking is by the Government, not private individuals, and is to obtain knowledge which is useful for the mining community. It is a practical step, however, which will surprise many in this country, where the mines do everything for the Government and the Government nothing for the mines. The idea of anything of the sort being done here to encourage the miners has never been entertained. But over there in the Australian colonies they encourage the miners in every way. They give rewards for the discovery of new fields, build roads to new camps, test peculiar ores, establish mining schools, publish practical information, and even assist in prospecting a field for the benefit of all. The miners there do not have to fight for fair play as do our silver and lead miners here. We could in this country take several leaves out of the mining books of the Australian colonies greatly to our own benefit.

Underground Temperature.

It is a well-known fact that there is a certain distance below the surface of the earth where the temperature is invariable throughout the year, and this invariable temperature is the mean temperature of the year on the surface at the place of observation; but on going down below this point the temperature increases in accordance with the peculiar conductivity of the rock, but in such a manner that the principle is imperfectly understood. Still it is known that some rocks are better conductors of heat than others; hence it is inferred that the class of rock in a certain locality will produce a higher temperature than other rocks of a different description.

In the coal mines of England the general increase of temperature has been found to average for the first 100 feet one degree for every 50 feet below the surface, for the second one degree for every 70 feet, and for the third 600 feet one degree for every 85 feet; but this is taken as the average and not as being uniform throughout. For instance, if the Rosebridge colliery be taken, Prof. Everett points out that for the first 1674 feet the temperature increased at the rate of one degree for every 57.7 feet, for the next 771 feet the increase was one degree for every 48.2 feet, and for the portion between 1815 feet and 2013 feet, a distance of only 198 feet, the temperature increased at the rate of one degree every 33 feet, while for the lower 1296 feet the temperature increased at the rate of one degree in every 54 feet.

Gold Mining in Victoria.

The gold-mining industry in the Colony of Victoria is in quite a flourishing condition, and an increased output is expected this year. The results of work in the last quarter of 1889 showed a product of 162,902 ounces of gold, being the highest yield for any individual quarter since 1887. Ballarat district has the largest yield and Ararat the smallest. Information was received by the mining registrars during the quarter showing the quantity of quartz crushed to be 193,053 tons, from which 97,726 ounces of gold were obtained, being an average of 10 dwt. 2 98 gr. per ton. The Gippsland district had the highest average, namely, 16 dwt. 7.06 gr., while that of Ballarat district (9 dwt. 0 33 gr.) was the smallest. It is noteworthy that the district Ballarat, having the lowest grade ore, produced the most gold and paid nearly double the dividends paid by any other district.

The area of auriferous ground worked upon during the quarter is estimated at 326 square miles (519 acres), which is about 2⅓ square miles less than that for the previous quarter.

During the quarter there were 24,047 miners engaged in gold mining throughout the colony, which was a decrease of 440 compared with the number at work the preceding quarter. In quartz mining 12 361 were employed and 11,686 in alluvial. The number of Europeans at work in both classes was 20,668, and of Chinese 3379, which, when compared with the previous quarter, shows a decrease of 271 and 169 respectively.

The ten deepest shafts in Victoria on the 31st December last were as follows: Lansell's 180 mine, Sandhurst, 2640 feet. Moonlight Company, Pleasant Creek, 2409 feet. Victoria Reef Quartz Company, Sandhurst, 2302 feet. Victory and Pandora Company, Sandhurst, 2300 feet. New Chum and Victoria Company, Sandhurst, 2228 feet. North Old Chum Company, Sandhurst, 2210 feet. Old Chum Company, Sandhurst, 2128 feet. Great Extended Hustler's Company, Sandhurst, 2040 feet. Garden Gully United Company, Sandhurst, 2040 feet. New Chum Railway Company, Sandhurst, 2040 feet.

The Mechanics' Fair.

The next industrial exhibition under the auspices of the Mechanic's Institute of this city, will open on September 18th and continue until October 25th. Mr. E. S. Culver, the secretary of the Institute, has been appointed superintendent of the fair. This gentleman has been connected in an official capacity with these annual fairs for a number of years past, and has the experience and energy to make him an excellent superintendent.

It is greatly to hoped that the industrial classes and manufacturers in California will come to the front on this occasion with their products. This is by no means a local, San Francisco fair, but intended to represent the industries of the whole State. This being the metropolis of California, is the proper place to hold such an exhibition, seeing as it does so large and constant an attendance. There is no other opportunity at all equaling it, for manufacturers and dealers to exhibit their wares to those to whom they must look as purchasers.

Space, power, light and visitors the exhibitor has without cost. All that is required of him is to place his goods in some sort of proper order, and the arrangement is left to himself. As an advertisement nothing could be cheaper or better. The big building is filled with a sight-seeing crowd night and day. All sorts and conditions of people go there—the rich, the poor and the intermediate class.

It is desirable that more of the manufacturing industries be represented than has been the case of late years. To this end, those persons interested in them should at once bestir themselves to prepare for an exhibit. There is plenty of time for this, but it will not do to put off preparations too long. To make a creditable exhibit each one should make arrangements some time in advance so that he will be ready on the opening day.

CALIFORNIA ELECTRICAL SOCIETY.—At the last meeting of the California Electrical Society the Committee on Location reported that they had leased two rooms on the second floor of the Murphy building, on the corner of Jones and Market streets. The committee's action was indorsed, and the society decided to make an appropriation out of its treasury toward furnishing the rooms with a laboratory and other useful things. M. Davis, L. L. Baker, and P. B. Cornwall, who were elected honorary members at a previous meeting of the society, sent letters, thanking the organization for the honor conferred upon them.

California Asbestos.

Asbestos is found usually in small quantities in very many localities in this country. The great difficulty connected with the economical mining of this substance, has been that the deposits are generally found in small pockets. Both hornblende and pyroxene asbestos occur, the former being the more common, though it is often difficult to distinguish between these varieties. Most of the bisilicates, excepting those containing much alumina, pass into the fibrous varieties, all of which are known as asbestos, though the term "amianthus" is sometimes applied to the finer and more silky kinds. The leading localities in which asbestos is found are in Georgia, New York, Maryland, New Jersey, Pennsylvania and Virginia.

There are many places in California and Nevada, where asbestine deposits are found. While the mineral in some of these localities occurs in great masses and is remarkable for its length of fiber, it has generally been lacking in fineness, flexibility, or other desirable qualities.

For these and other reasons, such as the cost of mining and transportation and the limited local demand, the home product has not been able to compete with imported or Eastern asbestos in the California market. Deposits of the different varieties of the mineral have been found at a number of other places in the Pacific States and Territories, but so few of these have ever been developed in regard to their value or character little is known. Asbestos seems to be abundant enough in this region, but it is difficult to find it in such a form as to be acceptable to the purchasers. A gentleman informed us last week that he had been for two months trying to find a good deposit of this mineral in California, so that he could either purchase the product or the claim. He had found nothing satisfactory. If any of our subscribers have a deposit of the fibrous variety, and will write to the PRESS, we will send the name and address of the parties desirous of purchasing.

As a rule, it may be stated that the American asbestos is inferior in textile qualities to that which comes from the province of Quebec, Canada, being more brittle and harsh in fiber as well as shorter, and is therefore not so well adapted to the manufacturing of spun and woven goods. There appears to be little difference between the domestic and foreign in point of fireproof qualities, though some manufacturers claim that the domestic asbestos will stand a higher degree of heat. The American is better adapted for making fireproof cements and paints for which purposes it is generally used, length of fiber being unessential. The Canadian is said to be the best for general use and the Italian best for textile purposes.

Asbestos is used in making liquid and fireproof paints, roofing, piston-packing, valve-packing, covering steam pipes and boilers, fireproof cements, sheet and roll mill-board flooring, felt, etc. It is often used in combination with hair felts and other substances.

Engineering Work on Mount Conness.

Prof. George Davidson of the U. S. Coast and Geodetic Survey has his telescope and camping outfit ready packed to start for Mount Conness the moment he learns that the advance party has reached the summit. The mountain is covered with snow, and the outfit for the trip has to be conveyed first in wagons, then on sleds, next on the backs of mules, and then to the summit on the backs of men.

Prof. Davidson will make the ascent for the purpose of taking observations for the great trianguiation survey of the United States that is being made every summer. The triangulation of the Atlantic and Gulf Coast is nearly completed, but the Pacific Coast will still take several years. The observations are taken only from the tops of high peaks and when finished will furnish an absolutely accurate survey of the coast countries.

Prof. Davidson will remain on Mt. Conness until the latter part of August.

Bowers' Roller Quartz Mill.

The distinguishing feature of the superiority of these rolls for crushing quartz and other hard substances, consists in the shape of the rolls, as shown in the engravings on page 1. They are highly recommended for either wet or dry crushing, and for silver, gold, cement, phosphate, or concentreting mills. The old Cornish rolls were in use for crushing ores long before the introdnotion of stamps; hut, owing to the fact, the faces of both the rolls soon wore concave, thus preventing them from crushing fine enough for metallurgical purposes, the introduction of stamps hecame necessary. In the Bowers' Roller mill one roll is made concave on its face, and the other is made convex on its face, which improvement, together with other details in construction, remove the objections to the Cornish rolls. The rolls in the Bower's Roller mill wear perfectly even and true on their faces, and will continue to do perfect work until the steel shells are worn so thin as to require removal. When the roll shells are worn out they can be removed and new shells substituted in a few minutes, making the machine as good as new.

This roller mill was invented and patented by a practical stamp-mill builder of thirteen years practical experience in designing and hoilding all kinds of dry and wet silver mills on the Pacific coast. He full well understands the constant attention required to keep tappets, cams, shoes and dies in order in a stamp mill; the small amount of ore that can be crushed per stamp in dry mills, and the great cost of stamps set up ready to run, and his efforts to meet and overcome these objections, as well as the faults of all roller mills hitherto used for this purpose, resulted in the invention named.

Mr. Bowers' Roller quartz mill is a good substantial machine, capable of reducing the hardest quartz with great rapidity, and affords great saving in space, power, labor, size of buildings, excavations, etc., as compared with stamps. These roller mills occupy only about one-sixteenth the space required for stamps to do the same work. The claim has been made by some that no crushing device could he made that would crush as fine as stamps, but the manufacturers claim that the tests thus far made show that Bowers' Roller quartz mill can crush fine enough to pass through a 100-mesh screen, while in practical stamp mill work 40 to 60-mesh is as fine as is ever used.

The claims of superiority made by its manufacturers for this machine may be summarized as follows:

It is considered a better mill than Stamps; their use reduces the entire cost of mill to about one-half the cost of a complete stamp mill; great saving in labor; great saving in power; reduces the entire cost of treating each ton of ore to a minimum, without in any way reducing the percentage of saving of the precious metals; it enables companies or private owners of mines to put in a mill, under circumstances which would not warrant the greatly increased cost of a stamp mill.

Stillwell & Bierce M'f'g Co. of Dayton, Ohio, are sole manufacturers of the Bowers' Quartz Roller mill, and will furnish additional information on application.

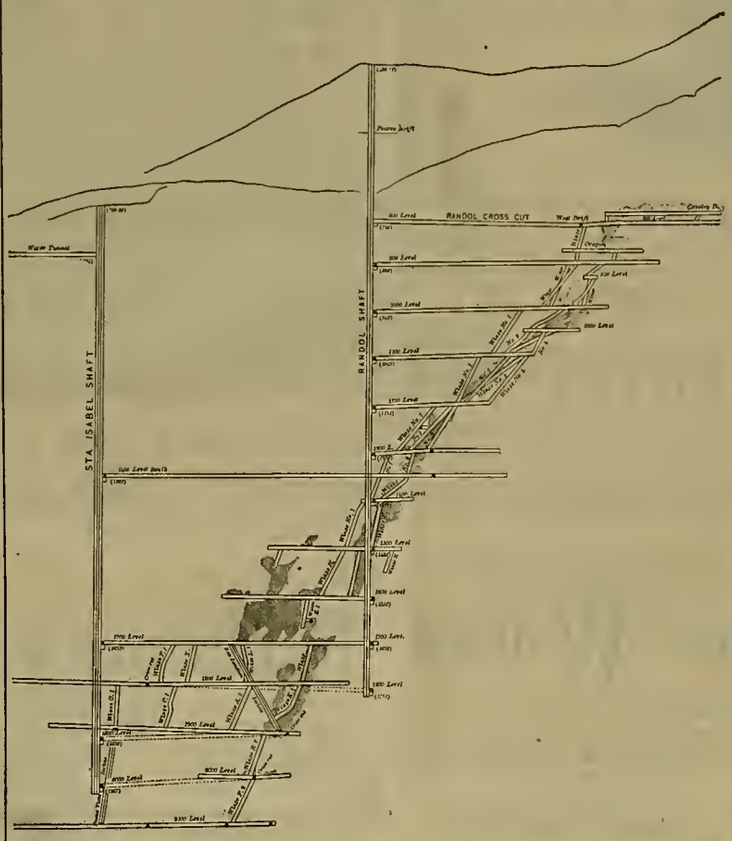
The New Almaden Quicksilver Mine

The surface and workings of the New Almaden quicksilver mine have been surveyed with the utmost care by the officers of the Quicksilver Mining Co., and data exist for the construction of any desired sections. A fine opportunity is thus afforded for a study of the structure of this most important deposit. In the MINING AND SCIENTIFIC PRESS of May 31 last were some sectional reviews of this famous mine taken from Dr. Becker's U. S. Geological Survey monograph on the Quicksilver Deposits of the Pacific Slope. On this page are two more sections cutting the northern portion of the mine or parallel north and south planes. One of them is taken through the Randol shaft and the other 350 feet west of it. The two are to be considered together. The eastern section through the shaft shows only the edge of the ore channel or that series of deposits which crops out on Mine Hill.

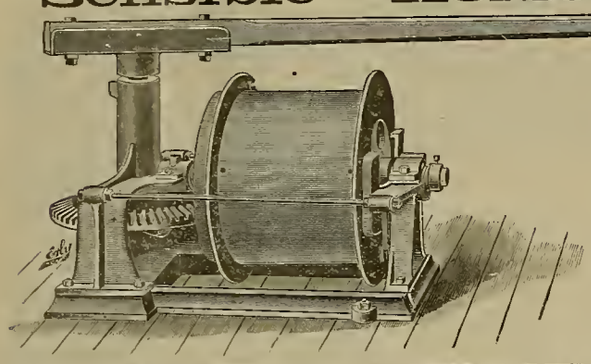
To this series belong the various Santa Rita "laborer" exhibited on the southern part of the section and the series of winzes extending from the Santa Rita to the 1400-foot level of the Randol shaft, showing here and there a small stope, sunk along the course of the same fissure. The main stopes on this section are on the north fissure, which divides the great body of rock forming the hanging country of the south fissure from the region north of the mine.

The quicksilver mines and reduction works of New Almaden are fifteen miles south of the city of San Jose, Santa Clara county, in the Santa Cruz mountains, at an elevation of 1700 feet above the sea. These mines were first worked for quicksilver in 1845, but the operations were on a small scale, and no record exists earlier than 1850. They have been the most productive quicksilver mines in the world, excepting only the mine of Almaden in Spain. They are developed to a depth of 2300 feet, and the workings extend horizontally over an area one mile square.

About 500 men find steady employment—the work being actively prosecuted throughout the year. From the 1st of January, 1864, to the 31st of December, 1889, the number of feet of drifting and sinking in the mines of the company, as shown by the records, amounted to 46.34 miles, at a cost of $2,067,862.63; this does not include the excavation made in extracting ore during the period named, nor any expenses for the same, while for the ground opened up during the previous period (from 1850 to 1864) 15 more miles of drifting and sinking can be added. The reduction works consist of eight furnaces, include the most improved methods for working quicksilver ores, and may be considered as the most complete and perfect in every respect in the world.



"Sensible" Horse Power Hoisting Whims.



These Hoisting Whims are built entirely of Iron and Steel, mounted on a heavy base plate, and, consequently, are very durable and cannot be affected by extremes of either cold or heat or climatic influences.

The hoisting drum is completely under the control of the person in charge of the hoisting or lowering through the shaft of the mine.

As the drum is entirely independent from the driving gears, the operations of hoisting, dumping bucket and lowering can be performed with the horse in constant motion, a feature not possessed by any other horse hoist in the market and one that greatly increases their capacity by avoiding the loss of time due to stopping and starting the horse.

They are very light and compact, and can be packed for transportation by mules. Their cost of erection is very slight; two men, in half a day, being able to put one in place, ready for work.

With each Whim, working drawings are furnished, showing in detail the proper construction of Gallows Frame and foundation for Hoisting Whim.

We carry in stock the following sizes:

No. 1.—Capacity with One Horse and Single Line, 800 pounds, 75 Feet per Minute.

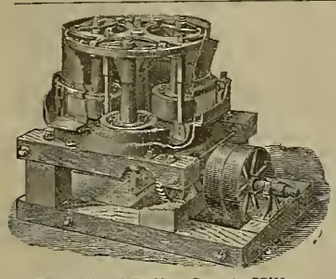
No. 2.—Capacity with One Horse and Single Line, 500 pounds, 125 Feet per Minute.

Weight of machine, 1200 pounds. Total shipping weight, including Sweep, Levers and Sheaves, 1400 pounds.

ROCK AND ORE CARS.

JOSHUA HENDY MACHINE WORKS,

NOS. 39 TO 51 FREMONT STREET, SAN FRANCISCO, CAL.



Centrifugal Roller Quartz Mill.

F. A. HUNTINGTON.

MANUFACTURER OF

CENTRIFUGAL ROLLER QUARTZ MILLS,

Concentrators and Ore Crushers,

Mining Machinery of Every Description. Steam Engines and Shingle Machines.

SEND FOR CIRCULAR.

213 FIRST STREET, SAN FRANCISCO, CAL.

VULCAN IRON WORKS,

135-145 Fremont St., San Francisco, Cal.

Mining Machinery. Steam Engines.

STAMP BATTERIES, PANS AND SETTLERS, ROCK BREAKERS, ETC., ETC.

SAW-MILL, CABLE-ROAD, REFRIGERATING } MACHINERY.

Special Machinery to Order.

AERIAL WIRE ROPEWAYS.

(Vulcan Patent System)

SINGLE, ENDLESS TRAVELING ROPE.

Elevated on Wooden Posts, from 150 to 2000 feet apart, conveying Buckets of Ore, Coal, Wood, etc.

No Possibility of Load Slipping.

Cheapest Form of Transportation.

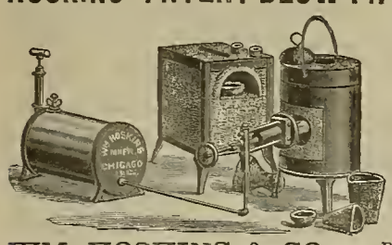
No road needed; can be run vertically. No power needed if angle of descent be more than 8 degrees.

CAN SPAN GULCHES 2000 FEET WIDE.

HOSKINS' PATENT BLOW-PIPE AND ASSAY FURNACES,

— FOR —

Chemists, Assayers, Metallurgists, Engineers, Jewelers, Dentists, Etc.



NO DUST! NO ASHES!

Portable! Practical! Automatic! Economical!

Will do for every thing that a Coal Furnace or Gas Furnace will, and WITHOUT A BLOWER.

Send for Price List and Descriptive Circular to

The Pittsburgh Boiler Scale Resolvent.

☞This Resolvent IS NOT AN EXPERIMENT but a FACT, and it will do the work claimed for it at a LESS EXPENSE than any other boiler purge, AND IN NO MANNER INJURE THE IRON.

CARNEGIE BROTHERS & CO., PROPRIETORS OF EDGAR THOMSON STEEL WORKS, PITTSBURGH, PA. WORKS AT BRADDOCK. Oct. 4, 1887.

We use the Pittsburgh "Boiler Scale Resolvent," and are well satisfied with the results obtained. We have tested nearly all Compounds presented to us, and this one **is the only good thing we have ever used.** Our feed-water is heated in Berryman Heaters, but owing to distance of heaters from boilers, we rarely exceed 150 degrees of heat in feed-water.

Our water is of the worst character, containing such bad impurities as **sulphate of lime, carbonate of lime, mud, and everything that is bad.** Very truly yours, WM. R. JONES, Gen. Supt.

No water in the United States produces scale in greater quantity or of a harder nature than the Monongahela River, containing SULPHATE and CARBONATE of lime, iron, MAGNESIA, SILICATE, SULPHUR, ALUMINUM, etc. The following well-known manufacturers, who are large steam users IN PITTSBURGH, and using the water from said river as boiler-feed for all their boilers, USE THIS RESOLVENT in their steam plant, and to whom reference is hereby made: Carnegie Brothers & Co., Proprietors of the Edgar Thomson Steel Works; Dilworth, Porter & Co.'s Spike Works; and Oliver and Robert's Wire Co.; and many other firms in the great manufacturing center WHERE THE RESOLVENT IS MADE. Reference is also given to Robert McMahon, Boiler Inspector for Alleghany Co., Penn., and to the following Railway Companies who use it on their locomotives: Kansas City, Fort Scott & Gulf Railroad; Central Iowa; Mexican Central; Delaware, Lackawanna & Western; Burlington, Cedar Rapids & Northern, Terre Haute & Indianapolis; Mexican National; and Denver & Rio Grande Western.

Upon receipt of order, WITH THE PROMISE OF FAITHFULLY CARRYING OUT THE PRINTED DIRECTIONS, we will furnish, FOR FIRST INTRODUCTION, a Barrel, or Half Barrel, of the Resolvent, and the invoice will bear the following stamp:

{ TO BE PAID FOR WHEN RESOLVENT PROVES ENTIRELY SATISFACTORY. }

FOR SALE ONLY BY

TATUM & BOWEN,

Sole Agents for the Pacific Coast,

Dealers in Improved Wood-Working Machinery,

Saw Mill Machinery, Engines, Boilers, Iron-Working Machinery, Supplies, Etc.,

Sole Agents for Hoe Chisel-Tooth Saw, Gardner Governor, Schultz Leather Belting, Etc., Etc.

34 & 36 Fremont St., San Francisco. 85 Front St., Portland, Or.

☞If in want of Machinery of any description, write us for Descriptive Circulars and Prices.

ADAMANTINE SHOES & DIES FOR STAMP MILLS.

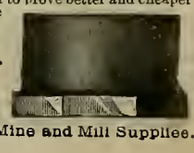
These SHOES and DIES are in extensive use in all the mining States and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited, subject to above conditions.

—MANUFACTURED BY—

CHROME STEEL WORKS, Brooklyn, N. Y.

H. D. MORRIS, Agent,

220 Fremont Street, San Francisco, Cal.



Special attention given to the purchase of Mine and Mill Supplies.

AMALCAMATING MACHINERY.

Stamp Mills for Wet or Dry Crushing. Huntington Centrifugal Quartz Mill. Drying Cylinders. Amalgamating Pans, Settlers, Agitators and Concentrators. Retorts, Bullion and Ingot Moulds, Conveyors, Elevators, Bruckners and Howell's Improved White's Roasting Furnaces, Etc.

FRASER & CHALMERS, MINING MACHINERY

CONCENTRATING MACHINERY.

Blake, Dodge and Comet Crushers, Cornish Crushing and Finishing Rolls, Hartz Plunger and Collom Jigs. Frue Vanner & Embrey Concentrators, Evans', Calumet, Collom's and Rittonger's Slime Tables. Trommels, Wire Cloth and Punched Plates. Ore Sample Grinders and Heberle Mills.

IMPROVED CORLISS AND SLIDE VALVE STEAM ENGINES. ❋ BOILERS HORIZONTAL, VERTICAL ...AND SECTIONAL....

IMPROVED STEAM STAMPS

Hoisting Engines, Safety Cages, Safety Hooks,

ORE CARS, WATER & ORE BUCKETS,

Air Compressors, Rock Drills, Etc.

BOISE CITY, CAPITAL OF IDAHO.

Metropolis and by provision of Constitution Permanent Capital. Unusual opportunities for investment and business. Capital needed. Mortgages net 10 per cent. Saw mills, brick kilns, woolen mills, iron works wanted. Unlimited water power. Best society, schools, churches. Perfect climate. Stock growers' paradise. Free Government Land. Great grain, fruit and vegetable country. Field crops net $25 per acre. Idaho, "Gem of the Mountains," will soon be a State. Third in precious minerals. Output last year, $17,000,000.00. Combine business with pleasure and visit us. Excursion rates.

IDAHO, "GEM OF THE MOUNTAINS."

Idaho's rapid increase in late years in mineral production is due to the scientific methods formed by capital and long experience. There is large opportunity throughout the mining districts of Idaho to develop mines with almost the certainty of large profits. Gold bullion is cashed at the Government assay office in Boise City. At the same time no mining field offers more attractive inducements to the hardy miner whose capital lies chiefly in his experience and in his pick. Full and complete information concerning Idaho mines will be mailed on application.

IRRIGATING CANALS.

Another great opportunity for capital in Idaho is in large irrigation enterprises. Projects are on foot to reclaim several hundred thousand acres, but there is room for many other such projects. Idaho has abundance of water, and the profits of irrigation are large and sure.

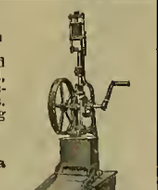
Day's Improved Quartz Stamp Mill.



This Mill is designed for the Prospector, the Assayer and Sampler of Gold and Silver-bearing rock. It is a perfect mill, built entirely of metals, and of the best mechanical construction; will amalgamate perfectly in the battery or on plates. It strikes a sharp, heavy blow with a light stamp. Shipping weight, 225 lbs. Price $75. Address

JAMES DAY,

ATLAS IRON WORKS, Cor. Napa and Louisiana Streets, Potrero, SAN FRANCISCO, CAL.

N. B.—CHAPPARELL, Butte Co., Cal., Nov. 10, 1889.—Mr. Jas. Day, Chico: The little mill is a daisy; it comes up to all expectations; it works perfect in all respects. Yours truly,
WALKER, REESE & CO.

ESTABLISHED 1866.

Pacific Chemical Works.

HENRY G. HANKS,

Practical and Industrial Chemist, Assayer and Geologist,

718 MONTGOMERY ST., - SAN FRANCISCO.

☞ Will report on the condition and value of any mining property on the Pacific Coast. Rare Chemicals made to order. Instructions given in Assaying and Practical Chemistry

THOMAS PRICE & SON,

Assay Office, Chemical Laboratory,

BULLION ROOMS and ORE FLOORS,

524 Sacramento Street, San Francisco, Cal.

COIN RETURNS ON ALL BULLION DEPOSITS IN 24 HOURS.

WORKING TESTS OF ORES BY ALL PROCESSES.

SPECIAL ATTENTION PAID TO CONCENTRATION OF ORES.

Ores Received on Consignment, Sampled, Assayed, and Disposed of in the Open Market to the Highest Bidder.

Metallurgy and Ores.

SELBY SMELTING and LEAD CO.,

416 Montgomery St., San Francisco.

GOLD AND SILVER REFINERY And Assay Office.

Highest Prices Paid for Gold, Silver and Lead Ores and Sulphurets.

MANUFACTURERS OF

BLUESTONE, LEAD PIPE, SHEET LEAD, SHOT, Etc., Etc.

ALSO MANUFACTURERS OF

Standard Shot-Gun Cartridges,

Under Chamberlin Patent.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.

63 & 65 First St., cor. Mission, San Francisco.

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scorifiers, etc., including, also, a full stock of Chemicals.

M.C.C.° BATTERSEA

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.

Agents for the **Morgan Crucible Co.**, Battersea, England. Also for **E. G. Denniston's** Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, July 3, 1890.

General trade the past week was of the usual holiday character which obtains at this season of the year. It is very generally conceded that the fall trade will be unusually large. This opinion is grounded on light stocks carried by interior dealers, good prices realized by farmers for fruits and prospective good prices for cereals, combined with more activity in the mining districts.

Money is fairly easy considering that tariff and silver legislation are still pending in Congress. The disbursements this month in dividends and interest will aggregate quite large, larger than in July of last year. The mining companies will pay out all of $200,000 less in dividends, but the various interest disbursements will be very large. The demand for money is not quite so pronounced as it was two months ago, but a gradual enlargement in the inquiry for funds is looked for after the present month.

The steamship Oceanic leaving this port on June 26th for Hongkong took out the following treasure: Mexican dollars, $211,175; gold coin, $8696, and gold-dust, $100; total, $219,97r.

MEXICAN DOLLARS—The market has held strong, but at unchanged prices, notwithstanding a slow demand.

SILVER—The local market has ruled quiet throughout the week. That the Mint was out of the market caused holders not pressed for money to withdraw from the market. It is very generally conceded that with the Mint again in the market, which will be next week, higher prices can be secured by sellers. The market has been unfavorably affected by the procrastination of Congress, and also by the general belief that Speaker Reed and the Administration are opposed, as far as practicacle, to legislation that will ultimately result in free coinage. Notwithstanding this opposition, persons in position to know are quite confident that a favorable silver bill will be passed by Congress sometime in this month. There is no disguising the fact that many prominent persons at the East who were formerly opposed to silver, are now looking more favorably upon bimetallism. It is the systematic course of enlightenment pursued by bimetallists that has won to them the many pronounced logical thinkers in this country, and which is also drawing to their standard many abroad who have been outspoken monometallists.

QUICKSILVER—Receipts the past week aggregate 225 flasks, and exports by sea 25 flasks to Sydney and 10 flasks to Auckland. The market continues strong. The supply is reported ample to meet all requirements. Receipts of quicksilver for the first six months aggregated in 1890, 6025 flasks; in 1889, 8205; in 1888, 14,076. The reports by sea and overland railroad for the liketime aggregated in 1890, 3857 flasks; in 1889, 5793; and in 1888, 7226.

BORAX—Receipts last week aggregated 257 ctls. The receipts at this port aggregate for the first six months of 1890 603,800; 1889, 2,505,600, and 1888, 4,398,800. The exports by sea and railroad out of the State aggregate for the like time as follows: 1890, 5,477 lbs; 1889, 3,340,221, and 1888, 2,703,779. The market is fairly steady at current quotations. Eastern advices report an active demand.

ANTIMONY—The market continues strong at full quotations. Eastern mail advices report firm markets.

LEAD—The market is strong. Eastern advices report a strong market, due largely to the reduction in importation of Mexican silver-lead ore. This reduction is about 2000 tons a month.

TIN—The market is strong at a slight advance for plate. The consumption is larger than it was heretofore claimed that it would be. The London advices to June 25th report that market affected by silver. With an advance in the latter metal, tin will do much better.

COPPER—The output on this coast does not show any material increase as yet, but a larger output is looked for the last half of the year. New York mail advices report "that mining companies name 17c as bottom price for Lake Superior Ingots or bars, and the best delivery offered is "July at sellers' convenience." Outside lots may probably be secured at 16¾c, but in limited quantities only. Arizona Ingot does not appear to be obtainable at less than 15½c. There is no unusually large demand for it at the present time, but the product is being used to greater or less extent in the place of Lake Ingot for some purchases, owing to the relatively high cost of the latter. Common casting copper is very firmly held at 14½c and selling very fairly.

A London cable to the *Iron Age* of June 26th reports as follows: Business in copper has continued large, at about £58 10s. for Merchant bars, and the position is steadily growing stronger. Stocks continue to be rapidly reduced, and if the present rate of decrease continues, the supply will be down to a dangerous level by December. When recent sales of American were completed the visible supply in England and France was only 60,000 tons, and the total now is but about 50,000 tons.

IRON—The market is without any essential change to note. The stocks here are liberal, with fair-sized consignments on the way. European advices report a lessening output which is creating a firmer market in England. Eastern advices report an easier undertone, although on the surface business is fairly active.

COAL.—Imports the past week aggregate as follows: From Kohe, 3100 tons, Nanaimo, 834 tons, Comox, 2350 tons, Seattle, 2275 tons; total, 8579 tons. In Cumberland there is an advance of $1 per ton for spot. The demand for steam coals is good, but for gas and household coals the inquiry is only fair. A better inquiry is expected to set in soon for household coals. The Wellington strike is not off yet. Australian coals to arrive are cared for, as are several cargoes now loading. For near shipments the market is strong, but for distant shipments it is easy. English coals for shipment are easier.

UNUSUAL activity is anticipated in Flowery district, Nev., when the litigation now pending is settled, as several mining locations on which work was suspended have pay ore in sight.

Eastern Metal Markets.

By Telegraph.

NEW YORK, July 2.—The following are the closing prices the past week:

	Silver in London.	Silver in New York.	Copper.	Lead.	Tin.
Thursday	47⅞	1 04¼	$16 65	$4 47½	$21 50
Friday	47⅞	1 04¼	16 35	4 52½	21 20

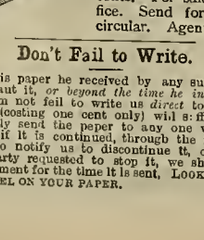
To Subscribers and Readers.



A HANDY PAPER BINDER—A. T. Dewey's patent elastic binder, for periodicals, music and other printed sheets, is the handiest, and very cheapest of all economical and practical file binders. Newspapers are quickly placed in it (as received) and held neatly, as in a cloth-bound book. It is durable, and so simple a child can use it. Price (size of this paper, Harper's Weekly, and Scientific American), 75 cents; postage 10 cents. Postpaid to purchasers of this paper, 50 cents. For sale at this office. Send for illustrated circular. Agents wanted.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, *or beyond the time he intends to pay for it*, let him not fail to write us *direct* to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the peper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

Mining Share Market.

The Comstock shares were fairly active at declining prices, up to Tuesday, when the market showed signs of having about touched bottom for the present. On the down grade, which was relieved by short-lived spasms of a revival, the ring had to buy large quantities of stock that were thrown out by the disgruntled public. There is no denying but the general public has no confidence in the stock market, and the ring has itself to blame for this feeling of distrust. If they would work the mines honestly, and not according to bow the stocks are held, then they could make more successful deals. The question now is, can the ring make a deal of any size, with the public feeling as they do? To attempt it they must have a mint of money, in order to take the stock they would be compelled to do at the higher prices that must be advanced. There is no doubt but the ring has large lines of stock that it would like to sell, and to attempt this at a profit, it is natural to conclude that they must advance the market by street points and wasb sales or cross orders on the two stock exchanges. The market closed to-day, Thursday, strong and higher.

In the outside stocks the Tuscarora held steady, but the Bodies made quite a little move, but what for no one appears to know, unless to collect assesments. In both the Bodie and Mono there is nothing new to report, but in the Bulwer they have struck a six-inch vein of good ore. The stock of the first named went up $1 a share, while the latter only advanced five cents a share.

A subscriber is informed that an employer is responsible for the acts of bis employee or agent, and therefore, the best legal advisers in this city say that the officers of a mining company, who are elected by the stockholders of a mine to look after their interests, can be held responsible for any illegal, or other acts of a superintendent of the mine. It is the duty of the officers to look after the workings of the mine, the milling of ore, etc., so as to prevent any stealings, or other wrong acts.

From the Comstocks the news is growing more interesting and encouraging. The Potosi winze is still the gamble. In sinking this winze so as to connect with the drift that is being run from the Ward shaft, the ore is liable to widen out to 10 or 12 feet, or it is liable to pinch out. If it widens then the stocks of Potosi and that the stocks of adjoining mines will advance, but if it pinches out then down they go. It appears to be an even gamble. In Sierra Nevada very interesting work is being done, as there is in Mexican. It is said that they will soon commence running for some rich ore, claimed to lie farther west in Con Virginia. The work going on in Best & Belcher is being closely watched, as that in Hale & Norcross, and that in several of the Gold Hill mines. Latest advices from Savage reported about 14 feet of ore in the 1300 Hale & Norcross north drift, assaying from $40 to $60 a ton. In running this drift they are liable to get in and out of ore a number of times. In Challenge they are said to be in interesting ground. From Yellow Jacket there are vague rumors of a decided improvement. In Crown Point on the 300 east stope they are in from 10 to 12 feet, ore going from $20 to $30 a ton. From Overman and Seg. Belcher good news comes to band; doubtless this is why they broke the stock. In Kentuck they expect soon to have the dead work finished so as to open up the 1000-foot level. On this level there is every encouragement of finding rich ore.

From the Tuscaroras we are advised that the mills will start up soon under favorable conditions. In several of the mines rich ore is being uncovered. From the Bodies there are reports that possibly they may start the mill up on low-grade ore. Owing to the heavy expense of milling, etc., the low-grade ore has not paid. From the Quijotoas the usual rosy-colored reports come to hand.

THE Martinez oannery sent a carload of salmon to St. Paul last week to fill an order that followed the sending to that city of a sample case.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, $3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

Van Drake's Experimental Machine Works.

It is of the utmost importance to inventors and experimenters that their models and fine work should be placed in the hands of an experienced and skilled man; one who can readily grasp their ideas and executs them with precision, who can assist them over difficulties when they arise, and who will turn out their work with dispatch and economy.

Mr. A. J. Van Drake's service in this line of business extends over a period of more than 30 years, 20 of which have been passed in this city. Many of the productions of his active brain and cunning handiwork are now in general use, both in the East and on this coast, as he was in earlier years employed in the Bridesburg Arsenal near Philadelphia, and also at the U. S. Mint in this city.

For several years Mr. Van Drake has been engaged in the manufacture of models, fine machine work, electrical appliances, etc., for which purpose he is amply equipped with a force of skilled assistants supplemented by the most perfect machinery. Among these may be mentioned a Brainard milling machine, with cutters costing over $1500, with other machines and tools of corresponding high grade.

Mr. Van Drake enjoys the confidence of those who have had dealings with him in years past, a feature of particular importance to inventors. His works are located at 203 Fremont street.

Tuerk Water Motor.

The Tuerk Hydraulic Power of Chicago, Ill., places an announcement in this issue, calling attention to their water motor. These machines are models of convenience and can be used in many places where other motors are not available. Note their advertisement and write for catalogue, mentioning the PRESS.

COOPER COURTICE of the U. S. Geological Survey has arrived from Washington. He is about to commence an investigation of the fossils found in various parts of the gold belt of California, with a view to determining certain geological questions.

Practical Treatise on Hydraulic Mining.

BY AUG. J. BOWIE, Ja.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, $5, post-paid For sale by DEWEY & Co., Publishers, 220 Market St., San Francisco.

SALT LAKE CITY!

ONE OF THE GREAT FIVE.

New York, Chicago, Denver, Salt Lake City and San Francisco.

Midway hatween Denver and San Francisco, 700 miles from either, with no rivals north to British Columbia or sauth to Old Mexico, **Salt Lake City** is destined to become ona of the great **Over-shadowing Commercial Centers** in the chain between New York and San Francis o.

The **recent mighty inflow of the best American blood** has **doubled** her populati n, begun the davelopment of **untold resources**, built up **strong churches** of a l eading d nomination s, created **charming social conditions**, fostered the public school system, **dir ected municipal improvements** and opened the **most profitable Business Investment, Manufacturing and Mining Opportunities ever presented** by a city that in three years will contain **over 100,000 people**, and before the end of the century several times that number.

MORE MINING CAPITAL NEEDED.

The resources of Utah as a mining region may be shown by the following from the books of the **ONTARIO SILVER MINING COMPANY, Park City, Utah** (near Salt Lake City):

Dividend paid, No. 166, to April 1st, 1890, $10,850,000.00; ore and bullion sold ta April 1st, 1890, $24 121.203 13. Incorporated January 1st, 1877. Capital Stock, 150,000 shares; par value of stock, $100.00 per share; market price of stock, $45.00 per share and upward. Average numher of men employed, 425. Value of improvements and property (inventory December 31st, 1889), $2 985,854.77.

The Company pays regular monthly dividends of $75,000.00 or 50 cents per share. Utah has numerous dividend payers on a large scale. There are many other mines that are partly developed that promise the richest returns, with sufficient capital. Within three months, coke from our own home coal (Castle Gate) has supplanted foreign coke in our lead smelters.

Salt Lake City is now one of the most delightful homes in the world, with a perfect climate, good society, churches and schools 50,000 population and growing rapidly. We will be pleased to correspond with mining men and capitalists and point the way to some specially inviting fields. We have many Mining capitalists here, who will cordially meet and aid new men Our field is large, there is room for all. For illustrated pamphlets, summer tourist rates, and specific information, address

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

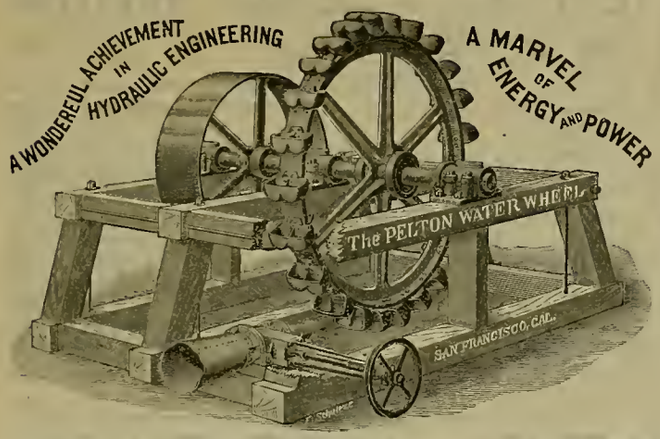
THE PELTON WATER WHEEL

GIVES THE HIGHEST EFFICIENCY OF ANY WHEEL IN THE WORLD.



A WONDERFUL ACHIEVEMENT IN HYDRAULIC ENGINEERING
A MARVEL OF ENERGY AND POWER
The PELTON WATER WHEEL
SAN FRANCISCO, CAL.

OVER 800 ALREADY IN USE.

Affords the Most Simple and Reliable Power for all Mining and Manufacturing Machinery.
Adapted to heads running from 20 up to 2 000 feet.
From 12 to 20 per cent better results guaranteed than can be produced from any other Wheel in the Country.

ELECTRIC TRANSMISSION.

Power from these Wheels can be transmitted long distances with small loss, and is now extensively used in all parts of the country for generating both power and light.

APPLICATIONS

Should state amount, and head of water, power required, and for what purpose; with approximate length of pipe; also, whether the application is with reference to *Wheels* or *Motors* described below. SEND FOR CIRCULARS.

The Pelton Water Wheel Co.
121 MAIN ST., SAN FRANCISCO, CAL.

IMPORTANT TO GOLD MINERS!

SILVER-PLATED AMALGAM PLATES for SAVING GOLD

IN QUARTZ, GRAVEL AND PLACER MINING.

PRICES GREATLY REDUCED.

Only Refined Silver and Best Copper used. Over 3000 Orders filled. Fifteen Medals Awarded. Old Mining Plates can be Replated. Old Plates Bought, or Gold Separated.

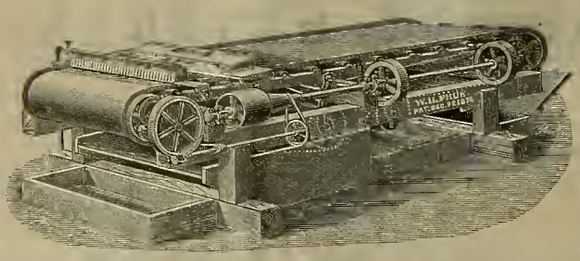
These Plates can also be purchased of JOHN TAYLOR & CO., Corner First and Mission Sts

San Francisco Gold, Silver and Nickel Plating Works, 653 & 655 Mission St., San Francisco, Cal., E. G. Denniston, Prop'r.

Our Plates have been used for 20 years. They have proved the best. We adhere strictly to contract in weight of Silver and Copper. SEND FOR CIRCULAR.

IMPROVED BELT FRUE ORE CONCENTRATOR.

The Best Ore Conceotrator in the market, having double the Capacity and doing its work as olose as the plain Belt machine, while its concentrations are clean. It is nsed in a numhar of Mills, the most notahle of which is the Alaska M. & M. Co's Mill, where 24 Improved Belt Frnes are taking the Pnlp from 120 Stamps, crushing 350 tons per day, and is giving entire satisfaction as against 48 plaio Belt Machiues, taking the Pulp from the other 120 Stamps.



Protected by Patents December 22, 1874; Septemher 2, 1879; April 27, 1880; Maroh 22, 1881; Fehrnary 20, 1883; Septemher 18, 1883; July 24, 1888. Patents applied for.

There are Over 2200 Plain Belt Machines now in Use.

Price of Improved Belt Frue Vanner, $825, f. o. b.
Price of Plain Belt Frue Vanner, $575, f. o. b.

For Pamphlets, Testimonials and further information apply at office.

THE MONTANA COMPANY (Limited), LONDON, October 8, 1885.
DEAR SIRS:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Youre truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction that 44 additional Frues and more stamps have been purchased. ADAMS & CARTER.

MANUFACTURERS OF ALL KINDS OF

Mining and Milling Machinery, Engines and Boilers,

SHEET-IRON WATER PIPE for Mining and Irrigation Purposes.

ALSO SAWMILL MACHINERY.

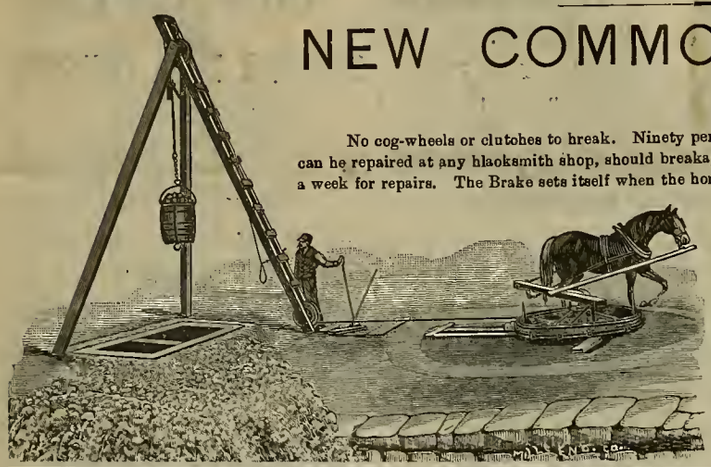
Exclusive Agents for the Pacific Coast of HEINE PATENT SAFETY BOILER and MACBETH STEEL PULLEY.

AGENTS FOR THE PACIFIC COAST OF

BRYAN'S ROLLER QUARTZ MILL.

NEW COMMON SENSE STEEL WHIM.

All Complete for $150.



No cog-wheels or clutches to hreak. Ninety per cent of this Whim is wronght iron and steel, and will spring or hend hefore hreaking, and hesides can he repaired at any hlacksmith shop, should breakage occnr, thus ohviating the necessity of sending away hundreds of miles sometimes, and waiting a week for repairs. The Brake sets itself when the horse stops or anything gives way.

It can he packed anywhere a jack can go, the heaviest piece weighing hut 100 ponnds; total weight, 650 ponnds. The sweep can he thrown out or in gear at any time, and the hucket hoisted, dnmped or lowered while the horse is in motion. It is just as safe and reliahle as an engine, and can he handled as readily, and is jnst the thing to open np a mine and make it pay. Spending thousands of dollars in fine machinery and shaft houses has "bnsted" many a company. Buy a COMMON SENSE WHIM, and when yon have got more ore than our Whim will hoist, then it is time to hny an engine, not hefore. It will save yon thousands of dollars if your mine should not pay. Being all iron except the sweep, it will not rot, warp, twist, or get ont of trne. Being wronght iron, it will not hreak in transportation. We also make Two, FOUR and EIGHT Horse Power Whims, Derrick Whims, and Boildiog Hoists, Ore Buckets, and everything pertaining to Horse Power Hoisting. State for what pnrpose, and at what place yon want to nse it.

☞ Come and see one at onr works in operation, or send for circnlar.

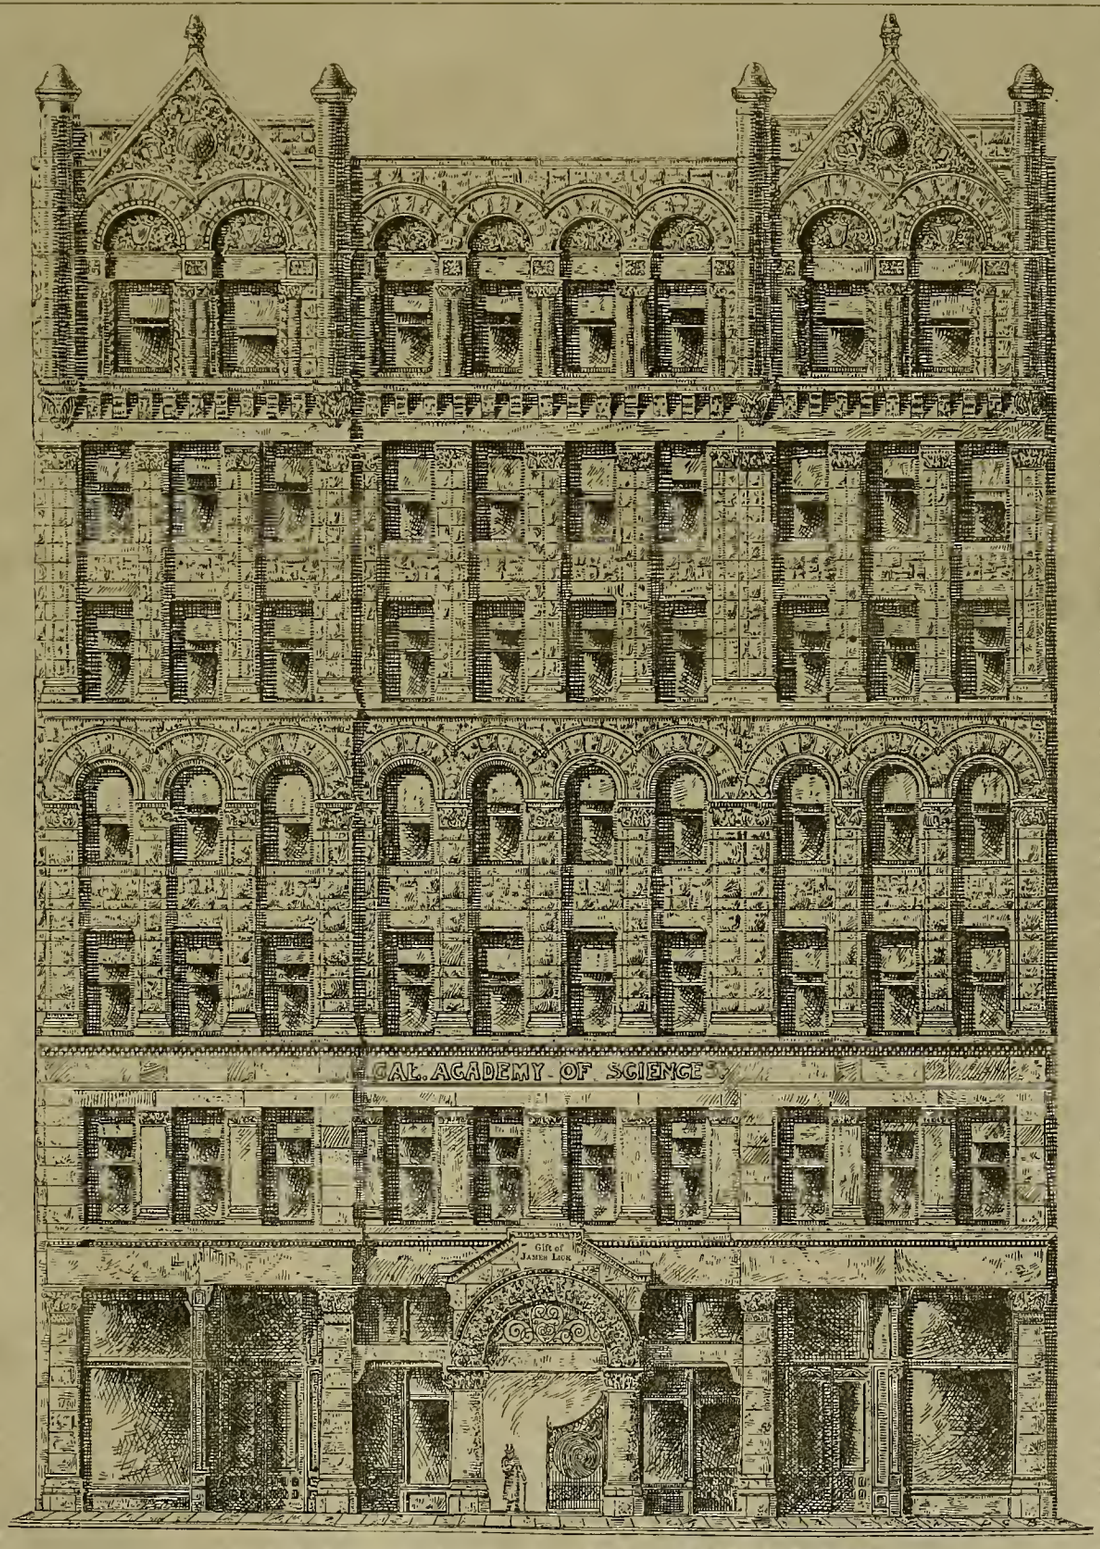
Academy of Sciences Building.

The late James Lick, among his many other benefactions, deeded to the California Academy of Sciences, some time before his death, a fine building lot on Market street, near Fourth. This is 80 feet front; it is 195 feet deep on one side and 275 feet on the other, being triangular at the rear end where it adjoins the lot of the Society of California Pioneers. The Academy of Sciences, being residuary legatees of the Lick estate, will receive some $300,000 or $400,000 in money on the settlement of the estate, and have obtained from the Lick trustees sufficient money to put up a very fine building, which is by far the best for scientific purposes on this side of the continent. In fact the Academy will shortly be better housed than any similar institution in the United States, thanks to the liberality of Mr. Lick.

On this page is presented an engraving of the new building now rapidly approaching completion. It was designed by Percy & Hamilton, architects, and is seven stories, or 112 feet, in hight. The building almost covers the entire lot, the exception being in the rear where the sharp angle of the triangle is cut off and the back wall of the new building forms an acute angle with the existing oblique wall of the Pioneer building, in order to permit of the insertion of windows along that side.

The entire front is of stone, for the first two stories gray granite, and for the upper ones sandstone in two colors. The accompanying sketch shows the character of the frontage. The ornamentation in the gables and other parts is in keeping with the objects for which the building is intended. Rich carvings at the cornices, pillar-caps, arches and pediment add greatly to the appearance of the building and make its substantial and durable stone front a thing of architectural beauty. The four walls really inclose two separate buildings, one an income-paying property of stores and offices, seven stories high, and the other behind it devoted entirely to the needs of the academy, a six-story structure. Immediately behind the rear wall of the front building is a light-well 27 feet in width and as long as the lot is wide, 80 feet, rising from the second story up, still more effectually marks the separation of the two buildings. The main and only entrance to both front and rear structure is from the Market-street front by a lofty, wide hallway, dividing the ground floor of the seven-story building into two parts for its entire length. The front building stands on the lot 80x88 feet, and will consist of stores and offices. There are four stores, a large and small one on each side of the entrance, the former being 20 feet wide in front and 31 feet in the rear, and the latter of small depth with a frontage of about 13 feet each. The offices of the upper floors are fitted as most modern offices are, electric wire bells, calls and all other customary conveniences being introduced in their proper places.



THE NEW BUILDING OF THE CALIFORNIA ACADEMY OF SCIENCES.

The finish is wood for the wainscoting of the corridors, doors and windows, as well as to some extent inside the different apartments. The partition walls inside the second story are of what is termed "slow-burning" or fire-resisting material.

The hallway on the ground floor is 12 feet wide, the entrance archway being elaborately carved and supported on double columns of polished granite, affording great depth and an imposing appearance. The floor is laid in colored tiles of picturesque design. The wainscoting for a hight of ten feet is of marble, and from that hight to the ceiling the walls are of different colored patent bricks with small arches and pilasters in relief. On the right side of the hallway, a marble and iron staircase six feet wide rises, and opposite it is a passenger elevator. The entire shaft is built in with brick walls

The Gold Belt of Northern California.

Ancient River Channels and Gravel Deposits.

NUMBER V.

[Written for the MINING AND SCIENTIFIC PRESS by JAMES F. TALBOTT, Shady Run, Placer Co.]

A short distance above is Prospect Cut (so named from the men working in the cut in grading the road, prospecting the gravel on their shovels and finding colors of gold). The view of the deposit in this cut, from the cars, is now obstructed by the snowshed over the track.

The lower end of the cut is in bedrock, which rises 100 feet above the railroad in a short distance to the south. The deposit consists of seven distinct layers deposited with great regularity in horizontal strata, each one of which is composed of different materials, with lines of connection as definitely marked as if made with a painter's brush in different colors, all forming the bank on the north side of the cut, 100 feet above the track.

About midway the cut is seen the first or bottom stratum on the bedrock, level with the track, composed of a solid light blue clay 15 feet thick, with many large volcanic bowlders imbedded in it. The next stratum above is a lava wash forming a kind of cement of rotten cobbles and bowlders about 20 feet thick. The deposit above this is a granite wash—sand, gravel, cobbles and bowlders, 20 feet thick. Some of the granite bowlders in this stratum are from five to ten feet in diameter.

This is suggestive of the time when this ancient channel was filling up from the granite country beyond Bear valley, for it is a well-known fact that there is not a foot of granite bedrock in place within 15 or 20 miles in any direction from this point.

On top of this granite wash is a deposit of a reddish-yellow clay, 15 feet thick, without a gravel or bowlder in it. Above this is a thin layer of white pipeclay. The next stratum is a mixture of coarse gray sand and light-colored clay ten feet thick. On top of this comes the main lava capping that caps the olimax. The margin of the lava has been graded off back to the depth of 20 or 30 feet. The character of the deposits inside the rimrock, as seen in the railroad cuts here described, is proof positive of the existence of a deep and extensive ancient channel in this ridge; and the method of deposit indicates in terms as positive the co-existence of the volcanic, the damming or blocking up and the eroding periods—alternating lava flows and floods. Here is seen the volcanic mud flow that forms the cement, a lava deposit on top of it. Then the water-worn gravel and bowlders, brought down by the succeeding flood and deposited on top of the lava. Then comes a commingled rush of lava flood that completely blocked up the channel below Prospect Cut.

The indications are that the lava ceased to flow for a time, and during this interval the floods got in their work, the result of which is seen in the deposits at Prospect Cut, and the numerous steep gulches, some of which have cut back inside the rimrock and carried away a portion of the deposits, leaving almost perpendicular cliffs of cement and lava. These and the deep gorge through which Blue Canyon now runs, are the unmistakable evidences of the modern erosions in action at the same time.

From Prospect Cut the railroad runs through bedrock cuts to within about a mile below the station of Blue Canyon, where it strikes into the lava, through a bluff point of which it runs in a tunnel about 500 feet in length. There are but few indications along here that would attract the notice of a superficial observer. Some quartz gravel and bowlders with a light sprinkle of gold, have been shoved over the rim, a little below the railroad track at China Ranch. A short distance above, where the railroad crosses the Cedar creek ditch, the cement is seen to crop out at the last point on this side the ridge.

This is a significant fact in support of the theory here advanced, when considered in connection with the surrounding conditions.

Here the Lava Flow

That is seen to cap the cement all along this ridge for miles below this point, crosses through to the North or Bear river side of the ridge. In exactly the same way, and through corresponding sections, three townships or about 20 miles to the south, the lava flow above Michigan Bluff crosses through the Forest Hill ridge to Damascus.

From the town of Blue Canyon the railroad curves around and cuts through high barren bedrock points, all the way to Emigrant Gap, where it leaves the gold belt of this section and climbs the steep and rugged mountains of bedrock and lava, to bring to view the wonders beyond.

To the south and intervening between this point where the lava crosses through the Shady Run ridge and Damascus, are Blue Canyon, the north and south branches of the North Fork, three deep canyons and two high barren bedrock ridges, and not a vestige of lava is seen between the two points. This fact alone precludes the possibility of any ancient channel crossing from this ridge to Damascus, as a great many mining experts have heretofore theorized. Before commencing a description of the north, or Canyon creek side of the ridge, I will briefly notice that portion of the channel that extends from the Hogsback, where the C. P. R. R. crosses through the ridge to Bogus Point (so named from a few rich spots, but no regular pay being found). This portion of the channel is about three miles in length, confined in a narrow gorge known as Moody ridge, between Canyon creek and the North Fork. A heavy lava cap covers the gravel and bowlder deposit, as shown at Bogus Point, where the channel gravel and lava have all been carried away by the present North Fork, similar to the channel of the Forest Hill ridge by the Middle Fork, below Spring Garden, as no traces of lava are found below this point. The high bluff of bedrock to the north of Giant's Gap, forms the south rim of the channel. On the Canyon creek side the rim rock extends well up to the top of the ridge in places, showing a lava deposit, at the widest point, about a mile in width and 500 or 600 feet in depth, inside the bedrock walls. Tracing the rim rock up on the south side of Canyon creek, we find just before reaching the Hogsback a narrow break from the ridge that lets out some of the gravel which formed a small deposit about Alta. A short distance above this break the bedrock rises above the C. P. R. R., as seen where it crosses the Canyon creek at Towles.

Following the same method, from the same motives adopted on the other side of the ridge, though not quite so comfortable, but with better opportunity for observation, we will put some dry goods boxes for seats on a flat car, take aboard the commission of geologists and mining experts to examine the north, or Canyon creek and Bear river, side of the Shady Run ridge, along Towle's narrow-gauge road. You will observe before we start that the track is on solid bedrock about 30 feet above the O. P. track, and a glance to the westward will show you that a spur of the same rises 100 feet above the track and extends half-way down to Alta. All aboard, off breaks, and we follow this spur of bedrock up on the

North Side of Canyon Creek,

About a mile, where it dips under a deposit of cement at Damagnard's old sawmill. Some small patches of nice-looking, fine gravel show along here. This body of cement undoubtedly extends through the ridge to Shady Run, as it is near the same level and capped with 500 or 600 feet of lava, as seen from this point on the south side of Canyon creek. The distance through is just a mile, or across one section. The indications are that at this point is an extensive break in the rim to the west, the outlet from which formed the gravel deposit of the Alta mine. This outlet unites with the one from the Hogsback, somewhere about Alta, and takes a northwest course toward Little Bear river, and formed the deposit at Nary Red. From this break-up to Towle's old Alabama mill, about a mile, the upper rim appears to have been carried away a little below the level of Canyon creek and considerable gravel carried over it and deposited about the head of Little Bear river. It is observed here that a spur of bedrock runs up between Little and the main Bear rivers. At the Alabama mill a deep and extensive break has occurred. A heavy body of cement is seen, capped with a spur of lava that has been cut off from the main ridge by Canyon creek. The outlet of this break extends in a northwest course to the main Bear river above the spur of bedrock referred to. On the south side of Bear river, on the line of the Gold Run branch of the South Yuba ditch, is seen a wall of cement and lava 200 feet high. Only a short distance from this point, above and below, the ditch runs in bedrock. The biggest pay ever found on Bear river was at Buffalo Slide, in the vicinity of this outlet.

A Short Distance Above

The Alabama mill, we come to where the Cedar creek ditch dumps the water into Canyon creek from the tunnel through the ridge just below Prospect Cut. Here we are about on a level with, and not more than half a mile from, the C. P. R. R., and a solid lava ridge 300 or 400 feet high is all that intervenes between the two roads. From this point, Towle's road runs to the northward some distance up Canyon creek, then ascends the bedrock ridge between Canyon creek and Bear river, crosses the summit and descends, in its serpentine course, over deep gulches and through abrupt bedrock spurs, to Bear River mill. From the mill, it climbs the steep, rough mountain of bedrock that forms the south rim of the channel in the Nevada ridge, north of Bear river. From where Towle's road descends the north side of the ridge between Canyon creek and Bear river, you will follow the Gold Run branch of the South Yuba ditch, or Culbertson's wagon road which is several hundred feet above the ditch, to get a correct idea of the high bedrock country lying between the Shady Run ridge and Bear river. For five or six miles along here there is not a trace of channel gravel or lava north of Canyon creek. The first appearance of any gravel or lava above is about the head of Dry creek. Some fine-looking gravel is seen on the South Yuba ditch and in some of the ravines. Here is a very

Extensive Break in the Rim

To the west—the last break on this side of the ridge—the outlet of which is into Bear river, about the old emigrant crossing. Many rich spots of pay, in coarse gold, have been found below, in the old channels of Bear river, some 20 or 30 feet below the present bed of the river. No pay has ever been found in the river above emigrant crossing. About the head of Dry creek, in one ravine, some pay was got, nuggets worth from $5 to $10 being found. A tunnel has been run here 500 or 600 feet, in a southeast course toward the lava ridge. The deposit on the bedrock is principally quartz gravel and small-sized bowlders intermixed with small pieces of flat slate bedrock, indicating beyond a doubt a deposit from a break, from the channel in the ridge, through the rimrock. From Dry creek, the Yuba ditch runs in bedrock to Bear valley—distance about three miles—and the Culbertson road, high above the ditch, runs on bedrock also. Scarcely a color of gold can be found in any gulch or ravine between Dry creek and Bear valley. It is from about the head of Dry creek where the channel runs through to the south side of the ridge, where it appears below Blue Canyon.

The Present Bear River

For several miles along here appears to have been cut out through a high barren bedrock country, lying between, or, that formed west rim of the Shady Run and Nevada Ridge channels. The bedrock rises abruptly from the river on either side. On the south, above Dry creek, it rises several hundred feet above the Culbertson road, and extends up to the lower end of Bear valley, where it dips to the east under a bed of lava, as seen on the south side of the valley.

On the north side of the river, just above Liberty Hill, the bedrock runs to the top of the ridge about on a level with the lava capping and extends unbroken (except one point where there is a break in the rim that formed a small gravel deposit known as Kinder's diggins) up to the lower end of Bear valley, where it dips—as on the south side—to the east under the wall of lava 800 feet high. This is seen just back of Jim Davies' house, on the north side of the valley. Near the lower end of the valley will be observed a reef of bedrock extending across from hill to hill. Going up the valley about half a mile one can see the decaying remains of a prospect plant. Here, 25 or 30 years ago, a company spent $10,000 to get down 80 feet into a bed of bowlders, for a little fine gold. Bedrock was not reached. Going up to the valley about half a mile farther you come to Jim Davies'. If you are dry you can get a glass of clear, cold water, that comes from 100 feet beneath the surface, out of the well in front of his house. No bedrock found here. I was told by Mr. Tompkins, who formerly owned the place and sunk this well, that the material passed through in sinking is a dark sandy loam, and from a few feet below the surface could be easily removed with a shovel. The most remarkable thing is the entire absence of any gravel or bowlders. A short distance above this well, you can see a few bedrock reefs crop out above the surface, running across the valley. Further up and to the east you will see spurs projecting out from either side, and rising from 50 to 100 feet above the valley. From those spurs to the east, the bedrock rises gradually for some distance, then ascends abruptly to the top of the hill, where it can be traced from Emigrant Gap, along the C. P. R. R. and north to and far beyond the South Yuba river 1000 feet above Bear valley and east of any gravel mines in this portion of the gold belt. Having traced

The Rimrock of the Channel

In the Shady Run Ridge, from Bogus Point to Bear valley, shown its extent and given the facts in regard to the conditions observed, I will now give the figures that define its course. Following the main lava flow inside the rimrock walls we see on the south side of Bear valley, in the southeast corner of Township 17 North, Range 11 East, altitude 4400 feet, a deposit of lava from 800 to 1000 feet high, above the level of the valley. This lava capping or flow enters from this point into the northeast corner of Township 16 North, Range 11 East, crosses diagonally through and out at the southwest corner, where it enters the northeast corner of Township 15 North, Range 10 East, about where the C. P. R. R. cuts through the ridge at Hogsback. From this point the flow continues the same course to Bogus Point, about the center of the last named township, altitude about 3000 feet. Where the lava channel and everything was carried away by the present North Fork, this lava flow can be definitely traced all the way from Bear valley to Bogus Point, within the lateral limits of every section through which it passes. There are but few places on the ridge where it is more than a mile in width. Several lateral spurs project from the main flow toward Bear river and Canyon creek, but the main flow is continuous in the course above stated, except a gap where the C. P. R. R. cuts through the ridge, there all of the lava and a portion of the cement has been carried away, on the south towards Green valley, on the north towards Alta. The conditions observed at Bear valley require more than a passing notice on account of the connection of the two ridges. The term "Divide," as used in this article, includes the country drained by one of the ancient rivers and tributaries, and the gravel deposits connected with them, independent of any other one. It will be perceived then, that the North Fork Divide is formed by the two main ridges uniting at Bear valley, there being no indications of any channel east of this point. The high bedrock country to the east and at the upper end of the valley, to the north, and the bedrock gorge through which Bear river now runs, to the west, has puzzled the most intelligent and practical mining experts of the Nevada Ridge. There appears to be a missing link here that the gold-hunter, with his magic dowsing-rod and hazel crotch, has failed to discover. About midway in Bear valley no bedrock has been found at the depth of 100 feet. At this point, about half a mile apart, rises on either side of the valley a wall of lava, 800 feet high. Evidence is abundant on every hand of some mighty flood that cut the gap through this bed of lava. It is evident no great amount of flood waters could accumulate from the drainage slope of the present Bear river, as it heads to the east in the gulches and ravines in the immediate vicinity, almost within rifle shot of the valley, at a standpoint where the south Yuba flume emerges from a gorge into the northeast portion of the valley. Looking to the northeast you can see coming toward you, on a direct line with the main Bear valley, the surging waters of the South Yuba river, roaring through the narrow gorges, with perpendicular and overhanging walls of solid granite hundreds of feet high. Leaping over and plunging around massive granite bowlders, the river comes down opposite, and but 200 or 300 feet beneath your feet, and here makes an abrupt bend to the northward and runs for miles in a gorge cut down 2000 feet in the solid bedrock. From all of the surroundings, it is obvious those floods were from the watershed, and that at no very remote period of time the waters of the South Yuba flowed down the channels in the Shady Run and Nevada Ridges.

(*To be Continued*)

The Mines of El Dorado County.

NUMBER II.

[By Our Own Correspondent]

Kalaay.

The Big Sandy quartz mine is operated by a Toledo company, with Mr. J. H. Beatty as superintendent. The property is opened by an open cut and tunnel on the large vein. The ten-stamp mill is running on their $2 ore. A shaft is going down to test the vein; so far the great size of the vein has not required a greater depth of working than 20 feet.

Dalmatia Mine.

This property is operated by a London syndicate, with Geo. C. Pearson as manager and N. H. Husband (formerly of the Eureka of Custer county, Col.) as superintendent. The vein is a huge mineralized dyke of porphyry, with quartz seams, and to all appearances is similar to the seam mines of the county. The mine is opened by tunnel and shafts which cut the ore body 200 feet deep. A crosscut 190 feet long has not reached the wall. The ores are mined by contract and delivered at the mill for 7½ cents a ton. This is made possible by reason of the large body of ore and its loose body character.

The mill is equipped with three Huntingtons, crushing 25 tons a day each, and ten stamps crushing 25 tons per day, making the capacity of the mill 100 tons every 24 hours. The Dalmatia is an exceptional property in several ways. First, in this: that their ore is *mined and milled for fifty cents a ton.* This a realization of things long hoped for by mining men.

While all mines may not contain as large bodies of ore so easily excavated still it opens up an unlimited amount of mining property low in grade, which at the present time is not worked in consequence of the expense exceeding the ore's value. This economy in the working of the Dalmatia mine ores is due to the fact that this property enjoys the distinction of being the first quartz mine in the State

Run by Electricity.

The electric plant is of the Brush patent. One mile from the mill the waters of Rock creek are carried down the American river and here 400 inches are turned on to a 7-foot Pelton wheel, with a pressure of 112½ feet. An electric generator of 126 horse-power is connected with the Pelton wheel. From this generator two wires run up over the mountain to its summit, and at the Dalmatia mill, one mile distant from the generator, connects with an electric motor or dynamo in the mill. From a pulley on the dynamo a belt carries the power direct to the main shaft. It seems almost incredible that the two small wires leading down to the dynamo should carry in them such wonderful power, and none the less wonderful that so small a dynamo should drive this large mill with its rock-breaker, three Huntingtons and 10 stamps, with perfect ease and not consume all its power. The company will now connect the old 20-stamp Gopher Boulder mill with the same wires and run it with their surplus power, making their capacity 150 tons a day. The mill has a complete electric light plant, with turbine wheels or three nozzles on the Peltons. A 30-foot fall will drive a dynamo, and the same water can be used continually as it flows down a river. In this way power can be created on any stream sufficient to drive all the mills within miles. It solves several problems. First, it reduces the cost in every instance; then, too, it allows the placing of the mill in any particular locality. It overcomes the difficulties attending the operating of a mine in those sections where wood and water are scarce, and while it saves all of the expense of water for boiler and fuel for heat it allows all of the water, in dry countries, to be used

for the batteries. There is scarcely any limit to the possibilities attending the use of electric power in mining, and it promises to be to the mining industry as great an advance as the steam engine over horse-power. No one contemplating the use of electricity should allow the fact that at this plant a large body of water under a great head is used, to discourage them, as the plant does not require either the quantity or pressure here used. The company had the water and the fall to use it. A visit of inspection will well repay any mining man, and I expect to see the Dalmatia the Mecca to which all progressive California mining men will be journeying in the near future.

Garden Valley.

The operations of the Taylor mine have infused new life into this section, and there is now every reason to believe that within another year this will be one of the best mining camps on the mother lode in the State. The mines are here. All they want is to be operated on the same scale, and to be as carefully equipped as in the Taylor, now known as the Idlewild G. M. Co. The main working shaft is down 500 feet on the vein, which runs from 4 to 30 feet. Previous millings of the ore gave an average of $8 a ton.

The mill has twenty 950-pound stamps, and is built to allow the placing of an additional 20 stamps. The ores are concentrated by the Woodbury concentrator, one concentrator to each battery, or four in all. Power is furnished by three Pelton wheels. The mill throughout is a model, and it would be a difficult matter to excel it. If there is any fault, it is this: the hoist is in the mill. This, while it is the rule should be the exception as in the case of any accident or fire, it is well nigh impossible to get the men out of the shaft. Messers. Hayward & Hobart make it a rule in all of their mines to have the hoist out in the clear with nothing but the frame over the shaft, and I think it would pay other mining men to follow their example. The Taylor system of water-supply is somewhat original in this, that lacking a site for reservoir to store surplus water, they have constructed a canal 800 feet long, 10 feet wide, and 6 feet deep along the summit of the mountain to act as a reservoir; this gives them a steady supply and 310 feet pressure at the mill.

Mr. E. W. Chapman is manager and Mr. W. E Denison, formerly of the Coffee creek hydraulic mine of Trinity county, superintendent.

The Reservation mine joins the Taylor, and is held under bond by them. The mine has a complete mill, and will, no doubt, be put in operation this season.

The Emma

Joins the Reservation. Mr. Bell, the owner, has for years past worked this mine for its pocket ore, sinking shafts over 100 feet deep single-handed. Now that the Taylor is coming to the front, he has every reason to believe that his property will prove a milling proposition. Up to this time he has confined himself to the quartz seams in the dyke occupying the lode.

The Lone Jack

Adjoins the Emma. This mine is opened to a depth of 416 feet, with a drift south of 100 and north of 80 feet on a ten foot vein. At present the mine and ten-stamp mill are idle, but will start up now that they can handle the water. Mr. H. Lawrence, formerly of the New Brunswick antimony mine, is superintendent.

Esparanza.

Mr. N. O. Burlingham is superintendent and has put the shaft down 200 feet and crosscut, showing the vein to be 54 feet between walls of ore that will mill $5 a ton. The ores carry one per cent of sulphurets running from $90 to $540 a ton.

Ivanhoa and Eclipse.

Mr. Fletter, of the California Cap Co., is operating the mines Ivanhoe and Eclipse. The work is all on the Ivanhoe. The vein has a diorite hanging and talc slate wall, with an exceptionally fine gouge. Throughout the length of the Ivanhoe numerous cuts and shafts show a strong vein. The main working shaft is down 200 feet. The mine has a complete hoist in good order, and only needs capital to make the property one of the best in the section. The former operators sunk 200 feet and then drifted 50 feet into the hard diorite hanging wall. The foot wall was not crossed to, nor was there any drift run on the vein. At other points on the vein the ore shows its mineral character, and throughout its entire course, with its croppings of from two to 20 feet, gives every indication of a good mine.

I know of no property where a small amount of money intelligently applied will be so apt to show up a good mine, and the property can be secured for a nominal sum, with privilege of first developing. El Dorado has a very promising future in her mining industry. Her past history is about to be repeated, and the quartz mines find the same El Dorado that first, through Marshall's discovery, drew attention to the gold of California. E. H. SCHAEFFLE.

THE proposition of incorporating several mining locations in Silver City district, Nev., and listing the stock on the San Francisco Stock and Exchange Board, is again being considered, now that the rate for listing has been reduced to one-half the former cost. So far none of the locations in that district have been explored to a depth of 500 feet except the Dayton and Kosmth.

San Bernardino County.

Its Mineral and Other Resources.

NUMBER I.

[Written for the PRESS by JAMES H. CROSSMAN.]

San Bernardino is the banner county of our State in area, if not in population and taxable property. It has within its boundaries all the elements of prosperity in great abundance. Its mineral and agricultural resources are probably unsurpassed by any county in our State. The division line is boldly and distinctly defined by that mountain chain known as the San Bernardino range. That portion best adapted to agricultural pursuits lies to the south, which is not void of mineral wealth, but the mineral region proper that forms the metallic domain of this county lies to the north of this mountain range. The northerly boundary of San Bernardino county is Inyo county, with the State of Nevada on the northeast, while the Colorado river which divides the State from the Territory of Arizona, forms its Eastern boundary. It is bounded on the south by San Diego county, while Los Angeles and Kern lie to the west. It contains within these boundary lines 23,476 square miles. Much of the largest portion of this area lies north and east of the San Bernardino range, of which there are of mountains and agricultural lands 6000 square miles, and of the so called "desert land" we find 17,476 square miles, a large portion of which is susceptible of cultivation, providing storage reservoirs, and artesian water can be obtained.

The Valley of San Bernardino,

Upon which Dame Nature has with such a liberal hand bestowed her bounteous gifts and blandest smiles, is already noted far and wide for its fertility of soil and picturesque landscape. It is situated directly east of the city of Los Angeles and about 50 miles south of west from the nearest point to the Pacific seaboard. The valley proper has a length east and west of about 60 miles, with an average width of 15 miles. We find here a varied combination of both soil and climate. It is here that the orange attains a greater degree of perfection than in any other locality on the Pacific Coast, as can also be said of all the varieties of deciduous and citrus fruits that are adapted to a semi-tropical clime. Clover, alfalfa, barley, wheat, oats, as well as every vegetable known to man, yield abundant crops of a superior quality. Walnuts, almonds, chestnuts, filberts, peanuts and pecans are also products of this favored soil, while the raisins grown beneath the benificent rays of the semi-tropical sun have a national reputation. It is the home of the grape. The wine manufactured in this county is highly esteemed and commanded a good price both at home and abroad.

Cities and Towns.

Outside of the city of San Bernardino are many beautiful and attractive suburban towns. The most prominent are Redlands, Lugonia, Riverside, Gladysta, Crafton, Banning, Mentone, Highland, Harlem, Old San Bernardino, Sunny Slope, Colton, Etiwanda, Rialto, Urbita, Cucamonga, Beaumont, Ontario, Terracina, Mound City, Chino, Rincon, South Riverside, East Riverside and Hermosa.

The climate in the valley is mild and equable, the thermometer seldom reaching the freezing point. About 17 inches of rain is the average.

Artesian Water

Can be obtained in many places both north and south of the San Bernardino range in both desert and valley. In the latter, 121 artesian wells alone furnish 13,000,000 gallons every 24 hours, while the combined annual flow is several billions. In San Bernardino and the adjoining valley over 400 of these streams are unceasingly contributing their quota of living water pure and crystalline. The pipes are from 2 to 12 inches in diameter; 300 wells are within the city limits. The principal source of supply to the Gage canal and irrigation system is drawn from this source. In addition to the supply from creeks and wells, reservoirs for the purpose of storing water have been built in the mountains. The lake formed by the Bear Valley dam makes the largest storing reservoir in State for irrigation purposes. We have taken the liberty of publishing the following description of this dam written by Elsen D Hall for the San Bernardino Board of Trade and published by that deserving institution illustrative of the resources of the county, at the same time acknowledging our obligations to Mr. J. C. Scott, secretary of that institution, for information and favors extended.

The Bear Valley Dam

Is located at the outlet of the Bear Valley into Bear creek, which empties into the Santa Ana about five miles below, and is one of the most favorable locations that could have been selected. The valley is surrounded by mountains, and has no other outlet but this, which here is very narrow with precipitous rocky sides. Into the solid rocks of this gorge the dam is abutted, and is built on a curve, arching inward, forming the arc of a circle, with a diameter of 345 feet. Its dimensions are: On top, 300 feet from abutments, 60 feet high from the bedrock of the creek in the highest point, and it conforms to the mountain slope on either side. Its base is 20 feet wide, and from this it slopes to three feet wide at the top. Its average coefficient of safety is 25, and it would stand twenty times its present pressure. The whole is built of vast granite blocks which were quarried near the margin of the lake and floated to the wall on scows, while a derrick built on a floating raft took them and placed them in position. The rocks were laid in Portland cement and all the interstices were filled with beton. The cement had to be hauled in wagons from Colton by way of the Cajon Pass and Mojave Desert, and thence down the valley to the dam, a distance of 100 miles. A four-horse team hauled eight barrels and it took ten days to make a round trip. Sixteen hundred barrels of cement were put into the dam at a cost of $13 per barrel, including the freightage.

The engineer was F. E. Brown of Redlands. The State Engineer of California has pronounced the work not only efficient but a remarkable piece of engineering.

The lake formed by the dam extends back into Bear valley over five miles, with an average width of nearly a mile, and a depth of 12 feet, and contains the enormous amount of 8,000,000,000 gallons. To supply this the valley furnishes over 60 square miles of drainage area, on which falls three times the amount of water which the lower valleys receive. The dam stands 6400 feet above sea level. The quantity of water held in reserve now is sufficient to irrigate 50,000 acres of land, and to supply a population of 500,000 with water for domestic purposes. Much water still goes to waste in Bear valley and elsewhere in the mountains. The capacity of this reservoir will be enlarged. Other dams will be built. Nowhere else in Southern California does so much rain and snow fall as on the San Bernardino mountains. The unfailing creek and rivers, the large number of flowing artesian wells, and the limitless supply of water in the lofty mountain valleys, which may be had for the expense of storage reservoirs, unite to make San Bernardino the best watered county in Southern California, we might almost say in the State.

The waters from Bear valley and other supplies in the mountains find their way by natural channels to the plains. At the mouth of the canyons, stone-lined ditches, flumes, and cement pipes convey the supply to the cultivated tracts. The best method of irrigating is to have a distributing reservoir into which the stream can run continuously, and be drawn upon as needed. Fruit lands need irrigating only about once in four to six weeks. After the ground is thoroughly soaked, two or three days are allowed to elapse before it is gone over with a horse cultivator. The surface of the ground is thus prevented from baking, and the moisture is retained for several weeks.

Transportation Facilities.

Two transcontinental railroads pass through the county, which, with the advent of the extension of the Utah Southern (now in process of construction at least as far as Pioche in Nevada) through the heart of the desert mineral region to some point on the Atlantic & Pacific R. R. or to tide water, would make three roads. These, with the California Central and the San Bernardino Valley R. R. now building, will make San Bernardino a railroad center of great importance. At date, San Bernardino is also the banner railroad county of the State, at least so far as mileage and county assessments are concerned. There are 417 miles of standard-gauge road and 321 miles of motor and narrow-gauge, with 21 miles of electric roads within its boundaries. These several companies pay assessments on $4,991,250, the value of the available railroad property in the State being $26,000,000.

Though the metallic domain proper lies to the north of the San Bernardino range, its valley region is not devoid of mineral wealth. The ores of tin of great value and immense quantity occur in the Temescal range of mountains, on the San Jacinto ranch; there are also mineral paint, gypsum, bituminous rock and coal measures. There has also been found a stone suitable for macadamizing streets. The manufacture of tiles and brick from a superior quality of fire-clay is an important and a growing industry.

Statistical.

For the following statistical data I am also indebted to I. C. Scott, Esq., Secretary of the Board of Trade of San Bernardino, and to Mr. Hale.

The tax levy for the year 1890 is $1.50 on the $100. The county is free from debt.

Acreage under cultivation for the year 1889, 64,410. The principal products were as follows:

	Value.
310,000 boxes oranges	$744,000
4,250 boxes lemons and limes	17,000
325,000 boxes raisins	546,250
650 tons dried fruit	143,000
40,000 cases canned goods	160,000
90,000 lbs. English walnuts and almonds	6,750
345,000 lbs. comb and extracted honey	23,300
240,000 gallons wines and brandy	63,000
275,000 centals barley	146, 50
Wheat, oats, hay, and other products	100,000
Total	$1,949,050
Minerals	1,350,000
Grand total	$3,299,050

Mr. Scott also states in his report to the Board of Trade for the fiscal year ending December, 1889, that the earnings of the county will average more than $100 to each man, woman and child in the county.

The above statistics, which can be relied upon as correct, show that San Bernardino county, taken from a financial standpoint, is now the leading county of the southern portion of the State. If she can do this with her paucity of inhabitants and undeveloped resources, what can she do with her plans for irrigation works completed, unimproved lands under cultivation and her desert regions pouring forth their treasures of mineral and metallic wealth.

Minerals in the Desert Regions.

From its present arid condition but little of the territory is suitable for agricultural purposes, without the assistance of artesian wells or storage reservoirs; but Mother Nature, ever prodigal, has sown broadcast over this dry region, immense stores of mineral wealth, rendering it the home of the miner and prospector, the advance guard of civilization. Of the many minerals and metals known, useful to man, there are very few that cannot be found in abundance, bituminous and carbonaceous products the exception. Intense volcanic action has destroyed all vestiges of inflammable materials, and the rocky structure shows everywhere the evidence of intense heat. At a very recent period in the geological history of the world, volcanic cones that ejected rivers of molten lava were in existence. The evolution of powerful gases and thermal waters through cracks, seams and fissures in the earth's crust, have, through chemical action on its mineral contents, metamorphosed and colored them with the bright hues of the rainbow, and all of their several shades harmoniously blended. The colors are vivid and pronounced; yellow, blue, black, red and white, with their several combinations and shades of purple, pink, lilac, green, brown, etc., the rocky structure either standing in vertical strata or on inclined planes, with thousands of acres of colored earth lying in a horizontal position at the base of the cliff, derived from the decomposition of the rock in places. The short mountain chains and isolated peaks, with which the desert region is dotted, are fissured with metalliferous veins of extraordinary richness. Here are gold-bearing veins, and veins charged with silver combinations. Copper is found in both a metallic form and as carbonates, oxides and sulphides. The ores of lead are found in veins and deposits of great strength and purity. The oxide of tin (cassiterite) is found, in placer, in immense quantities. San Bernardino, at no distant day, will be to the United States what Cornwall has been to Great Britain.

The most valuable of all of the ores of iron magnetites occurs in the Mojave district, enclosed in vein-shaped fissures from 20 to 100 feet in width, this ore assaying from 60 to 85 per cent metallic iron, free from phosphates of sulphur, only requiring the "iron horse" for transportation of the ore to fuel or of fuel to the ore, rendering us independent of the foreign product. There are alkaline earths and saline products, soda and borax, in inexhaustible quantities, the latter not only on and near the surface as an efflorescence but in vein-shaped deposits of remarkable purity and great strength. Full particulars of this remarkable deposit will be given under its appropriate head. These minerals and their metallic products with cheap means of transportation will eventually prove very profitable. The discovery and production of borax that abounds in this region was the factor that reduced its price from 65c. to 6½c. per pound, its present quotation. Large surface areas are covered with rock salt that penetrate to unknown depths and are of a crystalization so pure that a printed page can be read through a cube of one foot of this product. The wagon road from Mojave to Furnace creek, built by Coleman & Co. for hauling borax from their mines in Death Valley to rail, was compelled to use cutting tools for a considerable distance before they could haul their wagons over this rough, hummocky saline material. Granite, marble and sandstone for structural and ornamental purposes can be found of a superior quality in this county. Asbestos and mineral earths suitable for paints are known to exist; and niter is reported to have been discovered. This immense treasure-house of metallic and mineral wealth has heretofore been but little developed for want of cheap transportation.

(To be Continued.)

MINING is very active in Montana. It is estimated by competent miners that there is double the amount of work being done on the quartz claims in the vicinity of Butte than during any previous year since quartz was discovered in that vicinity. Especially is this true of the locations north of the city, where at least 150 are in course of development, two-thirds of which are paying propositions. As for the others, all that is necessary to make them such is development work, which is progressing as fast as steam and horse-power can accomplish it.

ANOTHER CHANCE FOR INVENTORS.—There is considerable complaint in some quarters about the annoying, rattling noise caused by the operating of type-writing machines, and it is positively disagreeable to persons in the same room who are compelled to tolerate it continually every day. There is no reason why a noiselessly operated machine should not be constructed. Let the inventors solve the problem.

EUGENE B. BURDICK, a well known mining man, formerly of Nevada but now superintendent of the Equator mine, near Placerville, El Dorado county, is visiting in this city. Mr. Burdick's recognized mining ability has been more than confirmed in the success he has met in opening up the Equator mine.

THE Hueneme *Herald* says there are 110 flowing artesian wells in that valley.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

QUARTZ.—Amador *Ledger*, July 5: A correspondent says that Monro Anise, while hunting stock in the vicinity of Quartz mountain, stumbled across a quartz ledge which promises to revolutionize mining in that neighborhood. Samples of the ore have been assayed, showing free gold in paying quantities, and sulphurets above the average. Three blasts of giant powder developed a ledge four feet wide on top, with slate for footwall, and a hanging-wall almost perpendicular. The lead has been traced for 1700 yards, and runs east and west.

CLINTON PEAK.—Messrs. Stevenson & Gutman of San Francisco have bonded of S. G. Spagnoli a tract of mining ground at Clinton, known as Clinton Peak. It is proposed to extend the tunnel now existing on the claim a distance of 150 or 200 feet farther. There is a quartz ledge from 8 to 10 feet wide, but the quality of the rock has never been tested by mill process. It is claimed by some that it will yield at least $4 per ton. Three men were started to work on the tunnel Monday morning. The Bingham mill, Pioneer district, is running on rock from Greisback's claim, with good results. It is thought it will prove a success. Two dollars per ton is charged for crushing. The batteries for the quartz-mill at the McKenzie mine passed through Jackson Thursday.

Fresno.

STRIKE IN THE HARRON.—*Expositor*, July 2: For nearly 30 years has old man James Harron's mine across what is known as the table and northeast of old Fort Miller in the Auberry valley, been crudely worked with varying fortunes to its owners. The mine is situated about 28 miles east of north from Fresno. It was worked before Harron became its owner many years ago. The claim was purchased from Mr. Harron by W. L. L. Witt and John C. Hoxey. In the summer of 1889 A. M. Clark and W. H. McKenzie, of the firm of Clark & McKenzie, bought an undivided interest in the mine from Mr. Witt and Mr. Hoxie, and proceeded to work it on a much larger scale than ever before known. The main vein of the Harron mine is composed of free milling gold quartz and varies in width from six to ten inches. During the score and a half years of mining operations in the valley this vein has been skimmed over by its various owners for 3000 feet, and in nearly every instance profit has accrued. The present company has sunk two shafts, each 100 feet in depth and four feet apart, to encounter the somewhat broken ledge. The methods of milling the ore are of the most primitive character, and comprise two arastras, to run which and get out the quartz, from five to ten men are constantly employed. This morning an *Expositor* reporter hearing that a rich body of ore, yielding $500 a ton had been struck in Auberry valley, he called upon Mr. Clark to ascertain the truth or falsity of the report. "Yes," said Mr. Clark, "about five or six days ago we struck a body of ore which goes $500 to the ton. In our judgment our prospects look very bright, but I don't care to have much noise made about it. The ore was struck near the old works and about 70 feet from the surface." In our drifting and stoping we have all along found free gold, giving from $75 to $400, and in some instances $500 a ton. The vein containing the gold is from six to ten inches wide. In many places the ledge is wider than this, but we don't care to work it, as it isn't profitable to do so. Mr. Witt is superintendent of the mine." The news of the strike has created considerable excitement in mining circles, and it in conjunction with the reported finding of the mother lode at Grub Gulch, is destined to give a boom to the industry.

Inyo.

PROSPECTING. — *Index*, July 2: Phil Cartier and Jo Diaz have started on a prospecting tour in the mountains far to the east of Independence. They fitted out for an absence of several months. Their objective point is a silver-lead prospect discovered by Mr. Cartier some time ago, samples of which assayed high in the hundreds.

Napa.

QUICKSILVER. — *Calistogian*, July 2: In the Black Bear quicksilver mine, where C. H. Nash, T. C. Brown and another miner have been working the past few weeks, the shaft is now down 60 feet. A drift from the shaft to the ore will soon be made.

Mono.

THE BODIE CON.—Bodie *Miner*, July 1: During the past week the winze from north drift, 200 level, was extended nine feet. Upraise from north intermediate drift above 400-foot level, was extended 9 feet. West crosscut from main north drift, 700 level, was extended 22 feet. There were employed nine miners and one foreman, and jointly with the Mono the west crosscut from south drift, 700-foot level, was extended 11 feet. There were employed two miners, one engineer, one carman and blacksmith, one assayer and carpenter, one watchman and one foreman.

MONO.—During the past week, jointly with Bodie, the west crosscut from south drift, 700 level, was extended 11 feet.

Nevada.

WASHINGTON.—Cor. Nevada *Transcript*, July 3: The Washington mine and mill at this place closed down to-day for a short time on account of shortage of water for pumping purposes. New steam hoisting works will be erected to take the place of water. Some immensely rich rock has just been taken out of this mine, and there is but little doubt that in the near future it will prove one of the most valuable mines in the county. The indications are strongly in favor of this outcome.

PEABODY.—*Tidings*, July 2: Monday evening Supt. Tilley brought to town some quartz specimens from the ledge in the Peabody shaft. The specimens included gold in crystalized quartz and gold in a band of quartz running through a piece of wall rock. Gold is also shown in quartz beautifully mineralized otherwise. The specimens are the handsomest seen here for some time, and coming as they do from the ledge in the shaft, on which sinking was recently instituted, verify our statements to the effect that we would not be surprised to bear of rich ore being extracted any time after sinking was commenced. The ledge is between three and four feet in size and aside from the specimens affords every indication of yielding profitably. The depth of the shaft is 215 feet. We expect to hear of these strikes in the Peabody occasionally, and the rich spots are just as likely to yield high up in the thousands as in the hundreds of dollars.

Placer.

THE ECLIPSE MINE.—*Republican*, July 2: The Eclipse ledge in Ophir district was first worked by Mexicans with an arastra in 1854. Nick Maring then worked it profitably for a time, but water which he could not manage caused him to abandon it. A. Shurtleff located the claim in 1869, and J. B. Patterson, the present superintendent, bought him out in 1870. Litigation followed, and the property was practically idle until a year ago last April. In the spring of 1889, C. A. Poage a capitalist of New York, became interested in the property and supplied the sinews of war for its development on modern lines of mining. Mr. Patterson has all along remained its active manager, and he put up what is doubtless the finest quartz-mill in Placer county. The building cost about $5000 and the machinery more than as much more. It contains ten stamps, but has room enough for ten more which will be put in this summer. There are also two Frue concentrators, and ample space has been provided to duplicate these as soon as the additional ten stamps are in place. The machinery is all run with Pelton wheels, and water from the Bear river ditch, which costs 12½ cents an inch by the year and is brought to the mill through 1000 feet of 15-inch pipe. Everything about the mill is new and complete. The Eclipse ledge is now being systematically worked under the direction of Ben Dunstan, foreman. The shaft is 250 feet deep, and it would almost be called an incline, since the ledge lies at an angle of about 30 degrees, and is comparatively flat. First-class hoisting works with a Cornish pump are over the shaft, and a small car attached to a cable drops you down into the mine. The quartz is good milling ore, and when a connection is made with the 130-foot level there will be plenty of good air all through the mine. The mill has been run steadily for about eight weeks; two cleanups have been made on about 350 tons of ore. The number of men employed at the Eclipse is about 30; the miners work eight-hour shifts and receive $3 a day. The ownership is vested in a stock company in which Mr. Patterson and Mr. Poage own the majority of stock. Mr. Pack, formerly connected with the San Francisco Mint, is assayer at the mine and has charge of the mill.

San Bernardino.

BLACK HAWK. — *Times-Index*, July 5: The Black Hawk mine started up on Monday last under the general management of Alex. Del Mar and the superintendency of Harry Del Mar. A force of 50 men were put at work for a starter. This move bids fair to make San Bernardino famous as a mineral-producing county.

San Diego.

MINES AND OWNERS. — Julian *Sentinel*, July 4: The mines that are now being worked in the camp are: The Owens, owned by King & Williams; the High Peak, owned by Barnett & Co.; the Gardner, owned by Robert Gardner; the Gold King and Queen, owned by the Gold King M. & M. Co.; the Helvetia, owned by Hubbell & Havermale; the Kentuck S., owned by the Julian G. M. & M. Co. of St. Louis; the Ready Relief and South Hubbard, owned by the Bailey Bros.; the Cincinnati Belle, owned by St. Louis parties; the Warlock, owned by Walker & Bell, and the famous Stonewall, owned by Gov. Waterman. Many smaller properties are being prospected, and many more are lying idle for want of capital.

THE MINING OUTLOOK of this camp is all that could be desired. Every individual and company is getting down to solid work. There are no idle men in camp, rich ledges are being uncovered, machinery is coming in. Investors are arriving to look the ground over and pick up "soft snaps," the croakers are disappearing and a general feeling of permanent prosperity pervades the camp. Some of our most prosperous ranchers have abandoned the plow and cultivator to take up the hammer and drill.

Siskiyou.

CINNABAR.—Yreka *Journal*, July 2: The Cinnabar mines on the west branch of Beaver creek, in the Siskiyou foothills, near the Oregon line, are to be worked on an extensive scale this summer, men of capital having bonded them with the intention of putting up new machinery, improved retorts and other necessary apparatus for securing quicksilver. The men engaged in developing these cinnabar claims, as well as on Beaver creek are experienced quicksilver miners, and will no doubt meet with the greatest success.

HYDRAULIC.—The Campbell hydraulic mine at Quicksilver Valley, and the hydraulic mines at Oro Fino, are all in successful operation, with an abundance of water to keep the miners busy day and night. About $21,000 in bullion from the Salmon river section was brought here last week for shipment below, and nearly $8000 was brought here yesterday from Know Nothing creek quartz mines in same section for similar purpose. The Salmon river mines, both quartz and placer, are turning out exceedingly rich this season. The river miners along the Klamath in the Honolulu section are all beginning to take out pay gravel, and down below at Oak Bar, will also be ready to do so after the Fourth, as their wing dams are about completed.

NEVADA.

Washoe District.

SIERRA NEVADA.—Virginia *Chronicle*, July 5: On the 630 level the west crosscut from the southwest drift, 600 feet from the shaft station, is advanced 374 feet, the face continuing in soft porphyry.

UNION CON.—On the 1465 level from the north lateral drift, opposite west crosscut No. 4, east crosscut No. 1 is advanced 537 feet. Continuing in porphyry and clay.

MEXICAN.—On the 1465 level at a point 70 feet south from west crosscut No. 4, west crosscut No. 5 is advanced 197 feet, continuing in soft porphyry.

OPHIR.—On the 1300 level the winze at a point 50 feet southwest of the raise is down 50 feet, cutting out station for a hoist engine.

CON. CALIFORNIA & VIRGINIA.—The 1300 and 1500 levels continue to yield the usual quantity of ore. There has been extracted during the week, from all parts of the mine 2367 tons and 430 pounds of ore. Shipped to the Morgan mill 97 tons and 440 pounds of ore and to the Eureka, 1490 tons and 1990 pounds; battery sample assays showing an average value of $18.23 per ton; [26 tons milled.] Sbipped bullion valued at $38,596.66 to the Carson Mint. On hand in assay office about $55,000.

SCORPION.—The southwest drift from the 660 level shaft station is advanced 655 feet and continues in clay and porphyry.

ANDES.—On the 420 level the north drift from west crosscut No. 2 is in 59 feet; formation quartz and porphyry.

SAVAGE.—Sbipped 495 tons of ore, showing an average value of $19.45 by battery sample assays.

HALE & NORCROSS.—Shipped 1102 tons of ore during the week, showing an average value of $20 per ton by battery sample assays. Bullion on hand valued at about $64,467.84.

WARD COMBINATION SHAFT.—The 1800 level east drift is out 490 feet; the face continues in porphyry.

CHOLLAR.—Extracted 500 tons of ore, battery sample assays showing a value of $22 per ton.

POTOSI.—On the 850 level east crosscut No. 4, 400 feet south of the north line is in 250 feet. The winze is down 212 feet on the slope below the 930 level, the bottom in fair-grade ore.

ALPHA.—The 600 level east crosscut is in 230 feet; the face continues in quartz. The 600 level west crosscut is in 298 feet, the face in quartz.

EXCHEQUER.—The 500 level north line east crosscut is in 296 feet, and continues in quartz and porphyry.

CON. NEW YORK.—The north drift from the top of the raise above the 800 level is out 120 feet; the face continues in low-grade quartz.

SILVER HILL.—The east drift from the winze below the 800 level is out 110 feet, the face showing bunches of quartz.

IMPERIAL. — The joint Confidence-Challenge 1000 level west crosscut No. 2 is in 169 feet, the face in low-grade quartz.

YELLOW JACKET.—Shipped 500 tons of ore showing average assay value of $20.50 by battery sample assays.

CROWN POINT.—Sbipped during the week 795 tons of ore, showing an average value of $17.08 per ton by pulp assays.

CONFIDENCE AND CHALLENGE.—The joint Imperial 1000 level north drift, from west crosscut No. 1 is out 118 feet, the face in low-grade quartz.

BELCHER.—The 1300 level east crosscut is showing streaks of quartz. The 850 level west crosscut is in 60 feet, quartz showing in the face.

SEG. BELCHER.—The raise above the 1000 level east crosscut No. 1 is up 140 feet, the top continuing in low-grade quartz.

JUSTICE.—During the week crushed 190 tons of ore showing a value of $27.50 per ton by battery sample assays.

ALTA.—The ore output this week was 360 tons, showing an average assay value of $23 per ton by pulp assays.

OVERMAN.—Shipped 485 tons of ore during the week showing an average value of $23.50 per ton by battery sample assays. The northwest drift continues in low-grade quartz. The incline winze is still sbowing ore.

UTAH.—On the 725 level the incline raise is up 185 feet above the south drift and has connected with the 600 level west crosscut. This connection forms an important airway.

OCCIDENTAL CON.—The 650 level main north drift is extended 170 feet, sbowing low-grade quartz. Crosscut No. 2 from the end of the drift is showing bunches of ore.

BEST & BELCHER.—On the 1000 level joint west crosscut No. 1 is extended 425 feet. Formation, hard porphyry. On the 1200 level west crosscut No. 4 is extended 63 feet. Formation, soft porphyry.

GOULD & CURRY.—On the 400 level the northwest drift is extended 165 feet. Formation, soft porphyry with streaks of quartz.

Cottonwood District.

NICKEL MINE.—Reese River *Reveille*, July 5: The lumber for the hoarding-house at the nickel mine on Cottonwood canyon has arrived on the ground, and the managers of the property expect to have the plant ready inside of two months to reduce the ore. Quite a number of men are now employed in extracting ore, there being about 500 tons of high-grade ore on the dump.

Eureka District.

ORE SHIPMENTS.—*Sentinel*, July 5: During the past week, the Eureka & Palisade railroad company shipped 390 tons of ore to the Salt Lake City smelters; also 155 tons of lead, making the entire shipments for the month of June 1455 tons.

Ely District.

THE PEACOCK.—White Pine *News*, July 2: Last Saturday, at the invitation of D. C. McQuitty, Major Treece and the *News* scribe jumped into his carryall and were driven across the valley and up the foothill grade to within 500 yards of the Peacock mine. Ten minutes' walk up a rather steep grade brought us to the mine. The flattering reports that had reached us from time to time of this new discovery, and of which mention has several times been made in the *News*, were more than corroborated by an inspection of the property and the surrounding formation. The outcroppings of this new discovery are a bold, regular, well defined quartzite, running east and west, with not a trace of lime to be found. Three openings have been made on the ledge, some distance apart, and the vein matter shows a brittle, decomposed quartz, carrying free gold that in some pieces of the rock can be seen with the naked eye. There is no question but that the vein is a true fissure, in fact, we have never seen so well defined a ledge in this county, except perhaps in the Star mine at Cherry creek. The cropping shows ledge matter for at least a width of 20 feet. The owners are now sinking a 6x6 foot shaft on the ledge, and were down 12 feet at the time of our visit. The material they are taking from the shaft is a lively quartz that will probably mill all through $20 per ton. The lowest assay made was $3, and the highest $130. Intermediate assays range between $10 and $50. But the owners are building no air castles on a high-grade mine. What they believe they have—and what all the indications warrant them in believing—is that they will open up an immense mine of $15 to $20 ore. The locators and owners of this promising property are: David Dennett, Thos. Johnson, Newton Boyd, A. G. McQuitty, J. R. McQuitty and D. C. McQuitty. The Peacock mine is situated about 7½ miles and a little north of east from Ely, in the foothills of the Schell Creek range.

Morey District.

RICH ORE.—Belmont *Courier*, July 3: The Morey M. Co.'s mine continues to yield rich ore. They have about 10 tons of silver ore in sacks that assays $2000 to the ton.

Pioche District.

ZERO.—Pioche *Record*, July 3: This is one of the claims of the P. C. Company lying south of the Raymond shaft, located on the manganese ledge there. In addition to the tunnel run last winter from the woodyard level at the Raymond Works, the company has a shaft on the vein 150 feet deep and are taking out a large quantity of fair quality ore. A 50-ton ore bin has just been erected, and the work is prosecuted by means of compressed air from the Raymond Works. Burleigh drills were used until a few days ago, when, on account of the comparative softness of the ground hand drilling was adopted. The company entertain great hopes of opening up a valuable property in this part of their possessions, and apparently not without good reason, the ledge at the bottom of the shaft now carrying three and a half feet of ore, two feet of which averages 108 ounces in silver, and one foot and a half 60 ounces, all free working ore.

HALF-MOON MINES.— The working force here now consists of 12 men, one-half of whom only are taking out ore, the others doing pure development work. Since our last mention the southeast or Re se tunnel has been run some 80 feet where the ledge now averages 20 inches in width, and from this point only all the Half-moon ore needed at the furnace is now taken, averaging 12 tons a day and assaying 29 ounces silver, 18 per cent lead and $9 in gold. Work continues on the north tunnel which is now in over 600 feet, and it is expected that 150 feet more on the north branch of it will be necessary to cut the ledge a second time. This tunnel will be used to work the ore from the southeast or Reese tunnel. The property looks well and is so developed now that 80 men could be put at work on ore at once if necessary.

Robinson District.

PROSPECTING.—White Pine *News*, July 2: A great deal of prospecting has been done in Robinson district so far this season, and the result has been satisfactory all around. There are now a dozen mines in the district fairly developed, and if their owners only had milling facilities they would ask no odds of any mining magnate in the world. But this is the last obstacle the prospector has to encounter. First he finds the mine, then he works it—sometimes for years—to show that he has it; but he may have ever so much pay ore, if it is not high grade enough to ship a thousand miles by wagon and rail he is but little better off than the first day he started out in the hills to look for the precious metal. There is great wealth of the precious metal in this district, and the work of the hardy prospectors for the past few months has brought much of it to light. What a pity that the mining experts who were here last winter, when everything was covered with snow, could not see our district now with the greatly improved features it presents. We may have to wait awhile, but the time will surely come when Robinson district, despite all drawbacks, will make its mark as a great gold producer. The mineral is here and it will be taken out.

ARIZONA.

NOTES.—Prescott *Journal-Miner*, July 5: Two pack trains arrived yesterday from the Bradshaw mountains with ore for the sampling works. The Oro Bella Co. will commence immediately prospecting for a water supply with which to run their mill. The Kansas City M. Co. have 11 men engaged in sinking a new shaft on the Silver King mine. They are now down to a depth of over 100 feet, and in good ore. Rich shipping ore was struck Thursday night last in the new shaft of the Silver King mine. With several shots put off Friday it improved, both in quantity and quality. The Silver King people are correspondingly jubilant over it. The Cinnabar claims of G. K. W. and R. C. McNary, in Copper Basin, continue to improve as development is made. Our correspondent at Camp Senator writes that surveys have been made recently there of the ground on which it is proposed to erect the new ten-stamp mill and concentrating works of the company. Machinery for this mill is now en route from Chicago. Two carloads of machinery arrived last night for the Copper Basin M. Co. It consists of a leaching machine and concentrating plant, and is an item of considerable significance to this country, as it means that the plant will be erected immediately in Copper Basin, and the camp started up in full blast. It is estimated that within three months from 200 to 300 men will be employed in Copper Basin.

COLORADO.

THE BUSHWHACKER AND ALPINE. — Aspen *Times*, July 3: The Taylor & Brunton tunnel people, when securing right of way for their tunnel through Smuggler mountain, neglected to secure right of way through the Bushwhacker and Alpine claims, then being operated by B. Clark Wheeler and others, and now controlled by the Bushwhacker M. Co. The tunnel company's contracts and rights extend as far as the Bushwbacker side line. It will be necessary for the tunnel company to make terms with the Bushwhacker company in order to make more than 1500 feet of their tunnel available on and along the great mineral run or contact. A co-operative contract will be of mutual benefit to the companies. The mining company desires to hoist ore from below the tunnel level by means of electric power, and to slide mineral down their incline from the levels above the line of the tunnel to the amount of millions of dollars, while the tunnel company must have right of way through the mining claims to satisfy the London stockholders, and to reap a reasonable reward on tolls for the transportation of mineral from the Bushwhacker and Alpine. Each company can do without the other, but a mutual contract will be of great value to both. The next property beyond the Alpine and Bushwhacker, on the line of the contact, is that of Iowa, Joplin and Cascade, controlled by the Iowa & Smuggler Mountain

M. Co. Manager B. Clark Wheeler says that his company will make an equitable contract with the tunnel company, if properly approached, after the Bushwhacker company arranges to give them right of way. Smuggler mountain will eventually produce many million dollars worth of mineral. When the Mollie Gibson, Standard, Park-Regent, Bushwhacker, Iowa, Empire, Champion and Mineral Farm properties are considered, the future for them and the great water-line tunnel is assured, and the owners of the properties will reap great wealth from their development.

DAKOTA.

COST OF THE BABY SMELTER.—Deadwood *Pioneer*, July 2: The cost of the D. & D. smelter has been greatly underestimated, as shown by the sworn statement of Mr. A. W. Coe. The cost of grading, building, etc., exclusive of grounds, machinery and freight on machinery, was $7798.32. The ground cost $4500, and adding machinery and freight, the total cost was not less than $15,000.

CHLORINATION WORKS.—The whole of the machinery from top to bottom, including the two recently lined roasters, was in operation yesterday, and running as smooth as could be desired. The men are all well trained to their several duties, and none are idle. Enlarging to a 50 or 60-ton plant is contemplated. All that is required is an additional chlorination tub, and this will reduce the cost of treatment to about $4 per ton. The process is a success and a gold saver.

IDAHO.

LOOKING WELL.—Idaho *Avalanche*, July 2: The Phillips & Sullivan mine is now looking better than ever, the lode being large and the ore proportionately rich. This mine has always produced good ore, a large quantity of which yet remains in sight.

WAGONTOWN.—The mines at Wagontown are all looking splendidly so far as worked; the more development work performed on them the better they look, especially as depth is attained. The Sommercamp Group is holding its own, and if anything, getting better. Very rich ore is now being taken from the winze being sunk on the large lode of this group. The Garfield is also holding the same rich ore that it did ten days since, much of which is being extracted for shipment.

CHAUTAUQUA.—This is one of the lodes comprising the Lepley group of mines, about half a mile northwesterly from the Wilson. The lode is now having development work performed upon it.

NYMPH is the name of a location owned by Mr. John Allington, Capt. G. B. Weeks and Mr. Dennis Sullivan. It is situated up what is known as Tom Wall's gulch. It is said to be about 50 feet wide. Work has been done in crosscutting, to tap the lode, for several months, and the end of the crosscut is yet fully 30 feet from the lode, but in a mass of iron.

STONDARD.—Work is still progressing in this mine, a drift being driven on the lode, which averages about 12 feet in width, carrying a great amount of low-grade gold ore.

THE Wilson mine is producing its usual amount of ore, keeping the DeLamar mill pounding away day and night. The ore is as good as usual, and is producing bullion right along.

LOWER CALIFORNIA.

NEW MACHINERY FOR ALAMO.—*Lower Californian*, July 3: The Princesa Co. at Alamo received on the Newbern from S. F. last week a big lot of machinery which will give mining in the camp a new impetus and increase the output of gold from the Princesa mines five-fold. The machinery includes a Knowles pump capable of throwing a four-inch stream, which is sufficient to drain any of the mines and render it easy to extract large quantities of rich ore. Besides the pump there are two boilers, one weighing five tons and of 50-horse power, one of 35-horse power, several trucks for carrying ore from the levels to the main shaft, an engine and various other machinery. The Princesa Co. is making solid progress under the wise management of Supt. H. W. Rodda, who is employing all modern contrivances to render the enterprise profitable to its owners.

PROSPEROUS.—Every little while a man is found who predicts the failure of the Alamo mines within a certain time, usually about three months, but the mines refuse to give out. The camp is highly prosperous and all indications point to its permanency.

THE CEDROS ISLAND MINE.—The Pacheco arrived this morning from Cedros with 2502 sacks of ore and nine passengers for San Diego. The steamer came in in a dense fog and literally felt her way up to the wharf from a point below Todos Santos island. She was compelled to leave 500 sacks of ore at Cedros, as the large force of men now at work at the mine are getting out ore faster than it can be transported, and four 4-mule teams are kept busy hauling to the steamer landing, a distance of three miles. Sixty-three men are employed in the mine and business is humming. New discoveries of gold and silver ore are reported on the island.

MONTANA.

ALICE.—*Inter-Mountain*, July 2: This mine is today in the hight of its glory, with every stamp dropping and silver ranging at the 1.06 figure. Developments are progressing on the 1300, 1200 and 1000 foot levels, and it may be said of a most favorable character under a superintendent whose mining capabilities has been the cause of bringing the Alice to its prominence as a bullion-producer, and its stability among the mines of the camp.

MEADERVILLE.—There are a number of small mines in the vicinity of Meaderville that are receiving the attention of leasers. From their continued operations and the pleasing countenances of those who have risked their chances on the uncertainty of mining, one is impelled to believe that all are prospering. It has been circulated that the boys in the Gambetta have met with some favorable indication in the bottom. All in connection with this property have been fortunate enough to strike it rich, all being hard-working young men. If they have a bonanza it is only what they deserve.

LOWLAND DISTRICT.—It is rumored that the Columbia mine is to be disposed of. This is the mine upon which James Coonan is erecting an arastra. It is about completed and ready to commence operations. The Ruby is in with the tunnel a distance of 530 feet, and the workmen expect to encounter the lead almost any day. This will give backs for stoping about 130 feet and will tend considerably to determine the value of the ledge as the shaft was sunk only a depth of 100 feet. Floyd, Brannigan & Co. are progressing favorably with their flume that is used for floating wood to Bernice. They are handling about 500 cords every 24 hours.

THE B. & B.'S 400-TON CONCENTRATOR.—The Butte & Boston Co. has contracted with Fraser & Chalmers to erect a 400-ton concentrator at Butte, near the smelter. The power will be derived from a 200-h. p. Corliss engine. The ore will be crushed by crushers and rollers, the lack of sufficient water preventing the erection of a steam stamp. The ore after crushing will be seiged both by trommels and hydraulic separators. After passing the jigs, the fine slimes will be treated on 20 Frue vanners. All the water will have to be pumped, and it is proposed to put in a Root rotary pump. The hight the water has to be raised is 75 feet. Before deciding on the pump best suited for this work, Supt. Palmer inspected the Root pump at the concentrator of the Butte Reduction Works. This pump raises 1200 gallons of water per minute a hight of 45 feet, and has been running constantly without a single breakdown for nearly a year.

NEW MEXICO.

LAST CHANCE SOLD.—Silver City *Sentinel* July 2: Through the indefatigable labors of John M. Wright, the Last Chance mine at Silver Creek, which was bonded last December, has been finally sold and cash purchase price of $25,000 was on last Saturday paid to the former owners, James Connery and Martin Johnson. The Last Chance people cheerfully admit the value of the other prominent mines of Silver Creek, notably the Maud S., Little Fannie, Deep Down, Confidence, Eberle, North Alpine, South Alpine, Consolidated and Champion, all of which are certain to become heavy producers in the near future. It is certain that the Last Chance sale is but the forerunner of several others of equal importance, and Silver Creek is liable to be one of the liveliest mining camps in the west before many months roll by.

NOTES.—Fully 70 men are now at work in the Hanover district, getting out zinc and silver ores. It is stated on good authority that arrangements are now being made looking toward starting up the Santa Rita works at an early date. Rufus Bennett has opened up his Willie mine at Hanover. This is a zinc property. It is said to be the cleanest carbonate zinc ore that has yet been tested.

ZINC.—The Hanover zinc mines are panning out better than at first expected. Twenty-two men are at work in the mines, with Mr. Snow superintending. The company is shipping as rapidly as it can get freighters and cars. The carbonates are being shipped to a Michigan company to be manufactured into paint. The "black jack" is being corded on the ground. This ingredient, otherwise known as zinc of commerce, is used in making zinc vessels and for other purposes. Judges of zinc ores say there are no zinc mines anywhere in the United States which will exceed in richness and quantity the zinc mines of Hanover.

OREGON.

GRAVEL MINES.—Baker City *Democrat*, July 2: The reporter visited the Nelson gravel mines Wednesday in company with D. W. C. Nelson and Paul Kemble. At the mine we were met by Samuel Baisley, manager in charge of the mines. The mine is worked by two giant hydraulics and a force of about 30 miners, assisted by about 2000 inches of water. The Big Aleck mine, operated by the White Star M. Co., Capt. Baxter, manager, was also visited and views taken of the mine and mill, which were in operation with a good showing of ore. The mill plant consists of a Griffin mill and Giroux amalgamator and both are said to work like a charm.

UTAH.

BINGHAM MINES.—*Inter Mountain Mining Review*, July 3: Mining matters are looking very bright at Bingham. Owners of prospects have begun development and there are more prospectors looking over the ground than at any one time for years. The price of lead and silver and the operations of the Niagara Mining and Smelting Co. are doing much toward developing the camp. The Rough and Ready, in the hands of leasers, is sending out some good ore. The Old Telegraph will make its shipments for June about 200 tons. The South Galena is doing its share in regular shipments. The Spanish is being worked by leasers, who are making shipments. This property, including its full group of mines, has this week been sold to Mr. Franklin for the Niagara Co. The Benton leasers are sending out ore in small lots, such as assay 40 per cent lead and 20 ounces silver. Mr. Eyre is getting a fine showing of ore from his Frisco mine. The Stewart mill started up last week, and after a three days' run made a very satisfactory cleanup of gold and then started the mill again. On the Brooklyn there is a reputed vein at the bottom of the shaft carrying eight feet of good ore.

WASHINGTON.

A SMELTER.—Spokane Falls *Review*, July 2: Some time ago it was reported in the *Review* that the Grant Smelter Co. of Denver, Colo., was considering the advisability of locating their smelter in this city. Information was given to the *Review* that shows such report is true, and that the smelter will soon be located in Spokane Falls. It has been known for some time that the Grant Smelter Co. have been looking out for a suitable site in this city, and that such was obtained a few days ago. The action of Mr. Chamberlain of Denver, in purchasing $170,000 worth of land goes to show that the company means business. The Grant smelter is one of the largest in the United States, and it is said that it can be run with less expense nearer the mines than where it is at present located, and it is mainly for this purpose that it will be removed to this city. The shipping of the ore to Denver and other points East not only consumes much time, but also adds considerable expense, owing to the long distance.

List of U. S. Patents for Pacific Coas Inventors.

Reported by Dewey & Co., Pioneer Pate Solicitors for Pacific Coast.

FOR WEEK ENDING JULY 1, 1890.

431,159.—OVEN DOOR—P. Abrahamson, S. F.

431,202.—SWINGING WINDOW—G. D. Crocker, Oakland, Cal.

431,162.—DAMPER FOR STEAM BOILERS—Geo. Cunningham, S. F.

431,259.—RAILWAY SPIKE—S. Emrick, S. F.

431,164.—ELEVATOR—F. Gutzkow, S. F.

431,165.—CAN PRINTING DEVICE—Chas. R. Hay, S. F.

431,476.—CLIP FOR WIRE ROPE WAYS—B. McIntyre, S. F.

431,483.—GANG EDGER—A. E. Roe, S. F.

431,198.—SHINGLE CUTTER—H. O. Strand, Montisano, Wash.

431,176.—FRUIT-GRADER—Geo. W. Thissell, Pleasant Valley, Cal.

431,303.—AUTOMATIC AIR BRAKE—G. B. Williams, Portland, Or.

431,304.—RELEASING ATTACHMENT FOR AIR BRAKE—G. B. Williams, Portland, Or.

The following brief list by telegraph, for July 8, will appear more complete on receipt of mail advices:

California—William Brooks, Oakland, broiler or toaster; Cornelius Butterbaugh, Los Angeles, car track; Frank M. Drelhelbis, Los Angeles, detractable horse-foot pad; Frank Koritick, S. F., combustion tool; Florence E. Monteverde, S. F., pump distributor; Samuel S. Richardson, Happy Camp, damper; Charles T. Stanford, S. F., device for operating elevator hatchway gates; James M. Thorpe, Santa Rosa, adjustable axle nut; Frederick B. West, S. F., cable sheave.

Oregon—George B. Williams, Portland, automatic air-brake.

Washington—William J. Burks, Seattle, headlight to locomotives.

Arizona—Thomas J. Thorp, assignor of one-half to D. J. Brennan, Flagstaff, horse-collar; Thomas J. Thorp, assignor of one-half to D. S. Brennan, Flagstaff, running gear for wagons.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

OVEN-DOOR.—Peter Abrahamson, S. F., No. 431,159. Dated July 1, 1890. This invention relates generally to the class of heating and fire-chambers, and especially to the doors thereof; and it consists of the novel arrangement and construction of the air-passages in the door. The object is to provide for a thorough ventilation of the oven or other chamber whereby its efficiency is greatly increased. Though the invention is applicable to the door of any heating or fire-chamber, it is specially useful for the oven-doors of stoves.

AUTOMATIC DAMPER FOR STEAM BOILERS.—Geo. Cumming, S. F. No. 431,162. Dated July 1, 1890. A chamber or vessel is employed of any suitable shape and size in which mercury is placed. When the pressure of steam in the boiler reaches any desired degree and it is desirable to close the damper and either wholly or partially shut off the draft, the pressure of steam acting upon the liquid in the chamber, through a system of plungers, rods and levers, acting upon the crank arm of the damper shaft, turns the damper so as to close it more or less, according to the hight to which the plunger has been raised. The damper being closed to any desired extent, which is determined by previous experiment. The fire will be correspondingly checked, and as the steam pressure decreases the plunger will descend and the valve will be opened, operating the damper, the operation being entirely automatic.

FRUIT-GRADER.—Geo. W. Thissell, Pleasant Valley, Solano county. No. 431,176. Dated July 1, 1890. This grader has grading-bars, which may be adjusted laterally. Bars or levers are also arranged so as to be turned upward between the inclined bars, and lift and move the fruit and prevent its sticking in the spaces between the grading-bars.

CAN-PRINTING DEVICE.—Chas. R. Hay, S. F. Assignor of one-half to R. H. Marchant. No. 431,165. Dated July 1, 1890. This is a novel device for printing upon the exterior surface of cans, and it is especially applicable to take the place of labels upon cans containing fruit, fish, or other substances, which are usually packed in hermetically sealed cans and afterward labeled by pasting paper labels upon them. By means of this device the inventor is enabled to print in colors upon cans with great rapidity, and the expense and time for putting on paper labels is avoided.

GANG EDGER.—Alpheus E. Roe, S. F., assignor to the Vulcan Iron Works. No. 431,483. Dated July 1, 1890. The points of novelty in this invention lie in the means for shifting the saws, the means for vertically moving the upper feed rolls, the means for holding them in desired position, and the means for driving them.

CLIP FOR WIRE ROPEWAYS.—Bartlett McIntire, S. F., assignor to the Vulcan Iron Works. No. 431,476. Dated July 1, 1890. This invention relates to that class of devices which are intended to be attached to or clamped upon a traveling wire rope, and to have attached to the other end a hanger for supporting a load, said devices being known as clips and forming part of a system of transmission by wire ropeways. The invention relates particularly to that class of these clips which are suitably formed at one end for engagement with the rope or cable, and at the other end for connection with the hanger which supports the load. The main object is to provide a clip which can be used with deeper faced pulleys than those in ordinary use, and also to provide in this connection a simple and effective clamping mechanism.

ELEVATOR.—Frederick Gutzkow, S. F. No. 431,164. Dated July 1, 1890. This is a hydraulic brake and speed regulator which is applicable to devices in which weights are raised and lowered by means of a rope, and especially to house elevators. It consists of a U-shaped tube containing liquid (such as mercury), a piston fitting loosely in one branch of the tube and connected from top and bottom with the top and bottom respectively of the elevator cage by ropes passing over suitably disposed guide-pulleys, and also for regulating passages through which the liquid moves with a retarded motion. The object is to secure the easy descent of the cage to the bottom if the hoisting-rope or machinery should break, and in general, a self-acting regulator of the speed of ascent and descent without the aid of mechanical attachments, levers or clutches.

Mining Share Market.

The mining share market has ruled fairly strong, but choppy. It looks very much as if the ring is selling stocks; yet they may not be, but only working the market so as to induce buying by outsiders who believe that the passage of a silver bill will inflate the market. It is not at all likely that the passage of a silver bill by Congress will help the Comstock mines as much as many think, for all present work appears to be in the direction of the west lode, which is nearly all gold-bearing. But if a silver bill is passed, it will help some of the outside mines. The public should not forget that until the Comstock mines are differently managed, they need not look for any movement in stocks based on merit, for the ring will continue the old game, "boodle for the ring and assessments for the outside public."

In outside stocks, the Tuscaroras are coming to the front, with Del Monte and Belle Isle the favorites. Bodie has been more active, at slight fluctuations. It is claimed that after the assessment is off, Bulwer and Mono will be assessed. It is also stated that some of the Comstock mining companies will levy assessments soon.

A subscriber asks why Overman, with $45,000 in the treasury, does not pay a 25-cent dividend. The stockholders, who have been paying assessments for years, may object to this money being used for manipulating purposes, as was the $200,000 left in the treasury of the Yellow Jacket when that mine went into the hands of the present management in July, 1883. A dividend had been declared at that time, and the new management rescinded it, and absorbed the money in the new style of milling that came into vogue at about that time.

The Virginia City *Chronicle* is authority for the statement that Levy, president, and Bob Keating, superintendent of the Savage mine, and also of the Hale and Norcross, gave a banquet at that place on July 4th, which lasted fully five hours. It is stated that at the banquet champagne flowed like water. Does this foreshadow an assessment by the Savage company? Perhaps both companies may levy assessments.

From the Comstock mines our correspondent writes that Overman is undoubtedly a mine and that well-informed miners are buying the stock. This is not the first time miners bought stocks on merit in a mine. Heretofore they "got left." How it will prove in this case remains to be seen. Our correspondent also reports a decided improvement in Chollar, in Con. Virginia and in Savage. The improvement in Con. Virginia is in the west workings and in Savage in the 1300 north drift. Where Chollar's improvement is he did not write. In Hale and Norcross on the 1250 level running west, they have cut the apex of an ore body. In Best and Belcher they are nearing the ore on the 1200-foot level near the Con. Virginia line. In Sierra Nevada and Mexican they are in interesting ground. Good reports ought soon to come to hand from the workings in Potosi. In old Belcher they are stoping out ore. In the other Gold Hill mines very interesting and encouraging work is being done.

News from the outside mines is still favorable from the Tuscaroras and Quijotoas.

We are officially informed that they are putting the pumps into place in Crown Point. It is expected that they will start up on July 20th, or at farthest by August 1st.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

KEYSTONE AUTOMATIC LIFE-SAVING CAR-COUPLING CO. OF CALIFORNIA. July 1. Object, to manufacture, sell and deal in life-saving car couplings, and particularly to manufacture and sell and deal in a certain car coupling invented and patented by Chas. A. McDougall of Alameda. Capital stock, $10,000,000. Directors—Lyman I. Mowry, Jas. S. Flood, J. W. Brown, E. Rocbart, J. C. Zellerbach, Wm. E. Bates and Chas. A. McDougall.

PACIFIC INVESTMENT CO., July 2. Capital stock, $1,000,000. Directors—F. F. Upton, T. H. Macdonald, C. B. Sessions, G. M. Crane, Joseph E. Green, G. W. Swain, A. M. Lusk, C. H. Reuter and W. I. Crossett of San Francisco.

ZENO MAUVAIS MUSIC CO., July 2. Capital stock, $80,000. Directors—Mae Mauvais, Nina Mauvais, R. L. Eames, J. G. Eames and Ella J. Stewart.

CENTRAL CANAL CO., July 2. Object, to improve irrigation facilities in Kern and Tulare counties. Capital stock, $3,000,000. Directors—Robt. McMurray, H. F. Culber, Geo. Easton, Geo. H. Maxwell and Geo. R. Wells.

TORPEDO STATION.—The Government engineers are building a torpedo station on Goat Island in San Francisco bay. The building will be of concrete, and cost about $20,000. All the torpedoes and other material used in the torpedo service on this coast, will be stored there.

MECHANICAL PROGRESS.

American Inventions Abroad.

The popularity of American machinery and other useful devices seems assured wherever it is put to the test—especially in comparison with those of European product. This assertion is fully verified by the unquestionable fact that the export of American machinery is rapidly increasing. The demand from abroad for

American Textile Machinery,

According to London *Engineering*, has of late been more active than ever before, and is undoubtedly to be attributed to the numerous patented improvements that have been and are constantly being added to American machines for cotton and woolen manufacturing, and which are now bringing them prominently to the front. These devices, the result of American ingenuity and invention, have been patented both in America and foreign countries, thus fully protecting the rights of inventors and manufacturers, and foreigners are not slow to recognize their merits. In the case of

The American Loom

This is especially true, for it is generally thought that for speed and good workmanship combined it is superior to all its foreign rivals. As a result it is being gradually introduced in many English factories, where practical test has clearly demonstrated its uses. In the United States the ring-spinning frames are largely taking the place of mules in many of the mills, and these are now beginning to force themselves upon the attention of foreign manufacturers, who, though slow to adopt new methods, and conservative in the extreme, cannot afford to neglect any improvements, from whatever source they may come, which will give them any advantage, however slight, over their competitors. The same is true with regard to many other machines used in the textile industry, in which the inventive genius of the New World has suggested valuable improvements over existing methods, and which are certain to come to the front in foreign countries as soon as their value is appreciated. During the past 12 months the value of cotton and woolen machinery exported from Boston alone has amounted to nearly $325,000, which shows an increase of almost $100,000 in comparison with the year previous. Our exports of machinery are far from being confined to the English markets. In addition to many other things,

The American Steam Fire Engine

Is to be introduced into Berlin, Germany. This is due to the recent visit of the officials of that city to America, in which a careful study was made of our fire apparatus. Such incidents as these show the grand importance of public exhibitions, mechanical and otherwise, which bring consumers and producers together. Other European countries are also looking more carefully than heretofore into the value of American machinery of different classes. The improved tools which are being introduced into our machine shops, the more deft manner of handling them and their more general use in supplanting hand labor than is practiced in Europe is enabling us to more than offset the great difference in the cost of labor there and here. This is especially noticeable in the

Comparative Cost of Our Locomotives.

When Bret Harte was American Consul in Glasgow one of his reports to our government brought this fact out very decidedly. His opinion then expressed is fully confirmed from official reports: A British locomotive-building company, noted for the fine equipment of tools used, and the advanced system of production followed, built 200 locomotives in 1889, while employing on an avarage 2500 men; a well-known American firm in the same time built 300 locomotives, while employing only 1400 workmen. Allowing 300 days for a year's work, the American firm puts the labor of one man for 1400 days on each engine finished. At the same rate the British builder puts the labor of one man for 3750 days on each locomotive sent out of the shop. The weight and power of the American locomotives greatly exceeded these built in the British shop. This is no hearsay matter. It was a comparison made by the chief executive officers of the two works referred to. The British firm follows largely the American practice of production by piecework, and the process of manufacture appeared to be very systematically carried on. There is, of course, a cause for the great difference in rapidity of turning out the finished machine. What that is may be nearly surmised.

American Machinery for Japan.

A New York firm has just turned out at Pittsburg and shipped to Hiogo, Japan, a complete plant for the manufacture of the camphor of commerce from the plants and wood fiber in which it is found in that country. The completion of the plant and its shipment may work a revolution in the manufacture of the drug. The plant, which is composed of stills, engines, boilers and other pieces, weighs 55 tons, and when shipped occupied two cars. Dr. A. G. Boyer, a prominent chemist, has been engaged for several years by the New York firm in trying to devise improved methods for the distillation of crude camphor into the articles of commerce, with a view of erecting a plant in Japan. He spent two months in Pittsburg, personally superintending the construction of the plant. He recently left this city (San Francisco) for Hiogo, where he will remain as chemical expert for three years.

What An American Saw in the Orient.

The New York *Congregationalist* recently published a very interesting letter from a correspondent who detailed what he saw while journeying through Central and Eastern Asia. We make a few extracts as follows: I saw advertisements for the sale of the Waterbury watch filling whole columns in newspapers and large spaces on the outer walls of buildings in all the great cities of India. I heard the hum of the American sewing machine in the byways and broad streets of Bombay and Calcutta and Rangoon. I saw American lamps for burning American petroleum hawked about the streets on wheelbarrows for sale in Yokohama and Tokio and Shanghai. I heard the clatter of the American typewriter in Chefu and Tientsin and Swatow and Amoy. I heard American dentistry praised as the best in the world, and I traveled with an American dentist who was on his way to practice his profession in the city of Peking. I afterward received his printed circular announcing his arrival in the great imperial city, and his readiness to extract the molars of mandarins or fill the cavities of Confucianists in the most approved style of American art.

I saw American tram cars running in the streets of Tokio, and the American windmill pumping water on the Bluffs of Yokohama. I was glad when I heard the click of Connecticut clocks keeping good time for Orientals who are always behind. California canned fruits and Oregon salmon and Boston baked beans in hotels all over the East, made me feel that home was not so very far away, and that the time was fast coming when one might compass the globe and find himself at home and among his own people, and hearing the familiar sounds of his mother tongue all the way. And the fact that America is so often represented in the East by the homely articles of practical and every-day use did not make me wish that my country had more works of fine art, or more ruins and traditions of ancient times.

STRUCTURAL IRON IN NEW ENGLAND.—In the past two or three years, the structural iron business in New England has undergone several changes. Formerly the bulk of the trade was in steam railroad work, but as New England has had sufficient track for the past two years, the call for this class of iron fell off, but was superseded by a heavy and improving demand in structural iron for buildings, in which the trade increased until last year, when the amount of business transacted in that line was unprecedented. A number of small contracts for thousands of tons were placed, and dealers were looking forward to a very good year in 1890. But in this they have been disappointed. The strike early in May dealt the business a blow which it will not be able to recover from this season. As it is, there is a fair business doing in iron for building purposes. Several large cities in New England were to be adorned with massive new buildings, the most important of which were Worcester, Springfield, Lynn and Lowell. Some very large contracts were placed this year. At present there are several large ones outstanding, in consequence of the labor troubles. The last two years in the structural iron trade have been rather peculiar and interesting. The decline of the steam-railway business was superseded by the demand for beams, girders, cast iron and other iron material consumed in the construction of large buildings, and in turn the decline in that business this year has given place to a substitute in the electric and street railway trade.

POSSIBILITIES OF INVENTION. — "When I first heard of a machine for driving spokes in wheels," says a writer in the *Age of Steel*, "my first idea was that such a machine could not be very profitable to employ. It takes but few blows to set a spoke 'solid home' by hand, and the machine could not possess the intelligence to know when the spoke was just home. I had known a most reputable firm of carriage makers to boast that their reputation was largely due to the fact that every spoke in their wheels had been driven by the senior member. When I came to see the machine driving 12 spokes in each wheel as well as they could be driven by hand, sawing them all off to equal lengths, and turning down the ends to fit the holes in the fellies, and doing all this to 300 wheels a day, my opinion of the value of that special machine underwent a radical change."

A NON EXPLOSIVE BOILER.—The members of the Breslau Engineers' Association inspected a non-explosive tubular boiler which had been constructed by Messrs. Stanislaus Lautner & Co. of Breslau. The danger of explosion is averted by means of automatic apertures, which slowly act when the steam exceeds a certain pressure, the water thereby being allowed to escape until the normal pressure is regained. The rapid water circulation in the vertically arranged tubes prevents incrustation and the deposit of mud.—*Kuhlow's German Trade Review.*

SUGAR IN STEAM BOILERS.—An engine driver at Bangalore, India, is said to have discovered that the slightest mixture of jaggery with the water used in boilers prevents incrustation. A pound of jaggery to 1000 gallons of water will suffice. Jaggery is a coarse kind of sugar made in the East Indies from the juice of the cocoanut palm tree.

SCIENTIFIC PROGRESS.

Recent Discoveries in Magnetism.

Dr. Hopkinson, President of the London Institution of Electrical Engineers, in a recent address before that body, alluded to some lately discovered and very curious facts in regard to magnetism which have thus far puzzled the scientists. The facts were referred to substantially as follows:

Why do iron, nickel and cobalt possess a property (strong magnetic susceptibility) which we find nowhere else in nature? that, so far as he knew, nothing that had ever been proposed even attempts to answer it. It is really one of the marvels of nature that there should be three bodies differing so enormously from all others in a matter of such great importance as magnetic susceptibility.

While it would interest only the physicist to follow in detail the developments in magnetic theory and knowledge, some very striking facts have been lately brought forward which should interest all, though at first they seem to obscure rather than to lighten the question above stated.

It is now pretty widely known that iron suddenly ceases to be magnetic when heated to the critical point of its "recalescence" or "after glow," and that if alloyed with some 12 per cent of manganese, as in manganese steel, it becomes almost completely non-magnetic. These facts show that iron is not necessarily magnetic under all conditions, for a mixture with a small quantity of another metal, and even mere change of temperature render it non-magnetic. Stranger still, some observers report that iron again becomes magnetic when the temperature reaches whiteness, but this lacks confirmation.

The behavior of nickel-steel is very remarkable. As usually received from the maker, nickel-steel with 25 per cent of nickel is non-magnetic, and yet it is a mixture of two magnetic metals, iron and nickel. If, now, we cool this nickel-steel to 20 degrees C., it becomes very decidedly magnetic, and remains so when it again returns to the normal temperature. If, finally, we heat it, it remains magnetic till it reaches its critical temperature of 580 degrees C, when it again becomes non-magnetic, and remains so until again cooled to 20 degrees C. In short, this nickel-steel may at the common temperature be either permanently magnetic or permanently non-magnetic as we please. We can at will make it permanently non-magnetic by heating it momentarily to 580 degrees C., and again cooling it, or permanently magnetic by cooling it temporarily to 20 degrees C.

Nickel steel has been recommended for shipbuilding because non magnetic; but if the nickel-steel ship is to become magnetic suddenly and without a word of warning on cooling to 20 degrees C., sending its compass spinning, its sphere of usefulness would be limited, for, though this temperature is not reached during common ocean trips, yet vessels in port in New York, Boston or Halifax, on the Great Lakes and elsewhere, are occasionally exposed to it. Reheating the vessel, to unmagnatize it, seems at first to present technical difficulties. Now, not only does cooling make 25 per cent nickel-steel magnetic, but it changes it from soft to hard.

Pull a bar of non-magnetic 25 per cent nickel-steel apart tensilely, and, presto, its broken fragments are magnetic!

This, be it understood, is the behavior of 25 per cent nickel-steel. It does not at all follow that, with other proportions of nickel, the same strange conduct will be found. Thus, with five per cent. of nickel, steel becomes non-magnetic when heated to about 800 degrees C. Like 25 per cent nickel-steel, it remains non-magnetic when cooled somewhat below this temperature, regaining its magnetism at a decidely lower temperature, but this lower temperature at which it again becomes magnetic, instead of being below zero, is somewhere about 650 degrees C. Again, it has become pretty well known that tungsten, itself unmagnetic, greatly increases the magnetism of steel; and now it turns out that it plays the same part with nickel, three per cent of tungsten making nickel more strongly magnetic than the steel of which magnets were formerly made. While tungsten raises the magnetic induction of steel from 700 to 5000 it raises that of nickel from 120 to 1032.

AN AIR BRUSH, as it is quite appropriately named, is the name of a device, which has recently been invented. It is used to throw pigments upon paper, very much as sand is thrown in the sand blast. The pigments are forced upon the paper or canvas through a flexible tube, by air which is condensed in a receiver by the aid of the foot and an air pump. The flow of the pigment is regulated by a valve, operated by the thumb, the tube being held and guided by the hand. It can be made to represent a fine line as in writing, or broadened out to any reasonable width of shading. It is claimed that one skilled in its use can produce a very excellent artistic effect, even in a portrait—one color only being used upon the background. If desired, the work can be finished up with the ordinary brush or pencil, employing the air brush only to do the drudgery. The effects produced by this instrument, in the hands of an expert, in a few minutes, can only be equalled by a band of expert toil by any other known process. In originality of conception, and in beauty and novelty of execution, it may be classed among the most remarkable of inventions, so it is said. The air brush is intended specially for working with India ink and water colors, and for applying lithographers' ink to the stone. Any color, or combination of colors, may be employed, presuming only that the pigments are liquid enough to flow readily. It is reported to work upon vellum and cloth without causing it to wrinkle, and to yield fine results on satin, tapestry, holting cloth, China silk and velvet. Its most obvious uses are as an aid to the artist in crayon and pastel work, especially in portraiture; in water-color work; to the photographer for finishing prints and re-touching negatives; to the lithographer as a labor-saver in placing the work on the stone, and in architectural, mechanical and engineering drawing, etc. This remarkable apparatus is manufactured by the Air Brush Manuf'g Co., of Rockford, Ill.

THE BIG IOWA METEOR.—On the evening of the 23 of May, as it is reported, the farmers living three or four miles southeast of Norway, Iowa, saw in the heavens an elongated, pear-shaped mass of dazzling whiteness. It seemed "as big as a mountain" to their excited vision, but intelligent observers agree that it was probably about 2000 feet long and 400 feet in diameter, with a tail of twice that length and much narrower across than the solid body. While the farmers gazed and wondered, it suddenly burst before their eyes. On going to the spot the next morning, where it appeared to have fallen, they found a space some three miles in length and a mile in width where great numbers of fragments had fallen and buried themselves in the earth. Search for fragments was immediately commenced, which resulted in finding a great number, the largest of which is said to have weighed 66 pounds, and was sold for $132. The story seems to bear evidence of truth.

ATMOSPHERIC ELECTRICITY — In the course of four years of experimenting, M. Albert Nodon has established the fact that when the sun's rays fall upon an insulated conductor, metal or carbon, they communicate thereto a positive electric charge, which increases with the intensity of radiations and decreases with the hygrometric state of air. At Paris the electrification is greatest at about 1 P M. when the air is clear and dry; but it disappears on the passage of clouds near the sun. The experiments indicate the source, or at least, one source, of atmospheric electricity, as it may be assumed that the surface of the earth becomes positively electrified, while the heated air rises with a negative charge which it imparts to the clouds. This hypothesis would explain many thunderstorm phenomena, including the frequency of such storms over forests, rivers, lakes etc., where the cooler air causes the electrified clouds to fall toward the earth until a discharge takes place.

COLD AIR ON TAP.—The Philadelphia *Record* is authority for the statement that capitalists in that city are about preparing to serve cold air about the city as gas or water is served. Chilled air is even now being furnished from a certain manufactory, to customers within a few blocks, and it is intended to nurse this little nucleus until a large and profitable system is hatched. It is proposed by laying the pipes deep and coating them with a non conducting substance, to force cold air from the central factory into market-houses, abattoirs, stores and even private residences.

FOGS AND ORCHIDS.—Fogs are highly prejudicial to orchids and tomatoes, according to a report presented to the Royal Horticultural Society by Dr. Oliver and Prof. Scott. This has been proved experimentally, and the society has determined to analyze the gloomy mists to find out the reason. The fact is that, besides other damage, they choke the "stomata," the breathing apparatus of plants, and years ago it was proved at the Royal Botanic Gardens that every season added to the list of fresh plants that could not live in London.

HOW POWDER SCORES GUN BORES. — The scoring of the bores of modern cannon by the new powders in use is claimed to be due to the fact that upon ignition all of the powder is not turned to gas, some of it remaining in a fluid state. It is this latter which does the scoring, by being thrown with such force against the metal of the gun that the resulting action is very similar to that of a sand blast for cutting glass.

DIFFERENCE IN TIDE LEVELS NEAR NEW YORK.—Observations of the tides of the Harlem at Forbam Landing with those of the Hudson at the mouth of Spuyten Duyvil Creek show that the level of mean high water in the Hudson is nearly a foot lower than in the Harlem, and that the mean rise and fall of the tide in the Hudson are a little more than two feet less than in the Harlem.

TWENTY ONE OBSERVATORIES are now engaged in the international undertaking of photographing the entire heavens. Each observatory will have to take about 700 photographs in the zone assigned to it, and it is hoped to finish the work in three or four years.

A NEW CALCULATING MACHINE.—A French mechanic by the name of Bollie has invented a calculating machine which adds, multiplies and divides with astonishing rapidity by the simple turning of a wheel.

GOOD HEALTH.

OLD AND YOUNG SHOULD NOT SLEEP TOGETHER.—A prominent medical writer says that no intelligent person who loves his children will allow them to sleep with persons greatly older than themselves. The nervous vitality of a child should not be absorbed by any diseased or aged relative or friend. Children, compared with adults, are electrically in a positive condition. The rapid changes which are going on in their little bodies abundantly generate and as extensively work up vital nervo-electric fluids. But when, by contact for long nights with elder and negative persons, the vitalizing electricity of their tender organizations is absorbed, they soon pine, grow pale, languid and dull, while their bed companions feel a correspondling invigoration. It is undeniable that healthful influences are lost, and to a fatal extent sometimes by this ill-advised custom. A woman was prostrated with inonrable consumption. Her infant occupied the same bed with her almost constantly day and night. The mother lingered for months on the verge of the grave, her demise being honrly expected. Still she lingered on, daily disproving the predictions of her medical attendants. The child, meanwhile, pined without any apparent disease. Its once fat little cheeks fell away with singular rapidity till every bone in its face was visible. Finally it had imparted to the mother its last spark of vitality and simultaneously both died.

MISTAKES.—It is a mistake to labor when you are not in a fit condition to do so; to think that the more a person eats the healthier and stronger he will become; to go to bed at midnight and rise at daybreak, and imagine that every hour taken from sleep is an hour gained; to imagine that, if a little work or exercise is good, a violent or prolonged exercise is better; to conclude that the smallest room in the house is large enough to sleep in; to eat as if you had only a minute to finish the meal in, or to eat without an appetite, or to continne after it has been satisfied, merely to please the taste; to believe that children can do as much work as grown people, and that the more hours they study the more they learn; to imagine that whatever remedy causes one to feel immediately better (as alcoholic stimulants) is good for the system, without regard to the after effects; to take off proper clothing out of season because you have become heated; to sleep exposed to a direct draft; to think any nostrum or patent medicine is a specific for all diseases.

SURGERY OF THE LUNGS.—In recent months surgeons have given astonishing proofs of the possibility of saving life and restoring health, in many cases, by removing portions of such vital organs as the brain and the liver. Prof. Tillmanns, of Leipsic, has found that surgical treatment may be extended even to the lungs, and to the arrest of consumption. In a case of tuberculosis of the left lung, an opening was made and the diseased part of the lung exposed, when that portion shriveled and was carefully removed. The patient recovered, and is now able to work. Prof. Tillmanns believes that this may prove a desirable treatment when the disease is localized, and states that two operations would doubtless be necessary—one to expose the affected part of the lung and bring about atrophy and shriveling, and a second to remove the parts after being functionally disabled.

THE OFFICE OF IRON IN THE BLOOD.—Iron exists in the blood in the red corpuscles, and gives them color and the power of absorbing gases. The fact that peroxide of iron is one of the readiest absorbents of gases, and parts with them as readily on exposure in thin layers to the air, so that it can be used over and over again for that work, gives a clew to its special function in the red corpuscles of the blood. It enables them readily to absorb oxygen as they pass along the minute blood-vessels of the lungs and to carry it to all parts of the body, where they part with it as it is demanded. It is supposed, also, to take up carbonic acid in exchange for the oxygen it yields up, and to convey to the lungs that portion of this substance which is expired.

COLORED SPECTACLES.—Dr. Konigstein, while giving directions in his class of the uses and prescribing of spectacles, said that green glass as a protection against strong rays was worse than useless, and did more harm to a sensitive eye than good, as they allowed the yellow rays to be transmitted and unnecessarily irritate the eye. As a protection against strong rays, the blue or smoked glasses were the only protection.

SOMETHING NEW IN SKIN-GRAFTING.—A schoolboy recently scalded his leg badly from knee to toe. As there were no signs of healing, the attending surgeon chloroformed a greyhound puppy to death, shaved its body, skinned it, and grafted the skin on the boy's leg. The healing was rapid, and the color of the grafted skin was uniform and very similar to that of the normal skin.

FOR TOOTHACHE.—A Russian practitioner recommends the use of hyoscyamus seeds for toothache. His plan is to burn the seeds, and to convey the smoke through a little paper tube to the hole in the tooth. He declares that in nearly all cases one application, or at most two, will suffice to cure the toothache.—*Lancet.*

THE BUILDER.

Causes of Decay in Stone Buildings.

Prof. Tetmajer of Zurich, one of the greatest living authorities on such subjects, made recently an investigation into the causes of decay of stone in buildings. According to recent authorities, the freezing of water in the pores of stone is the principal cause of disintegration. Contrary to the common idea, the most porous stones are, if properly used, not necessarily most subject to disintegration. If the water falling on the stone has a chance to escape freely, frost will not injure it, but if the movement of the water in the pores is checked, so that it accumulates anywhere, the freezing of this accumulation will gradually destroy even a strong stone. Proof of this may be found in nearly all buildings faced with sandstone or limestone. If the base or water table, or even a belt at any height is of harder stone, the freestone just above it will be found to disintegrate after a few years, owing to the checking of the downward movement of the water in the pores. So, on the underside of a projecting molding, or balcony, where the water accumulates by gravitation, but is prevented by capillary attraction from dropping off, flakes of stone will soon be observed to separate and fall; and soft stone near the ground, where moisture drawn up from the earth by capillary attraction with the double effect of the rain, and the spattering of rain water from the ground, keep it particularly moist, soon perishes. The decay of stone shows itself in two ways. With a stratified stone the frost dislodges flakes and plates, by working in the natural seams, but with a massive, homogeneous stone, the effect of freezing is to dissever the particles of sand, or the crystals of carbonate of lime, so that, although the stone may for a long time hold together nearly in its original shape, the rubbing of the hand will dislodge a shower of sand, and the profiles and arrises insensibly lose their sharpness.—*American Architect.*

PANELLED IRON CEILINGS.—Patent panelled iron ceilings have been before the public for the past eight or ten years, and now there are thousands in use, scattered all over the Union. In stores, banking offices and hotels, while their superior acoustic properties have brought them into extensive demand for churches, halls and opera houses. Their low cost and cleanliness introduce them into schools and asylums. And now the increasing demand for something to take the place of plaster for residence ceilings, something that would gratify the artistic taste of our most cultivated housewives, and still be permanent and enduring, and thus save them the constant annoyance and expense of replastering and repapering; something that could be applied over the old broken plastered ceilings without being compelled to take down and remove the dirt and dust-covering stuff, has prompted the makers to bring out beautiful designs of embossed metal plates. These embossed plates are adapted to side walls as well as ceilings, working up beautifully into wainscoting, frieze and field. As all figures and designs are in relief, really very little brush decoration is needed. They are, however, susceptible of any desired degree of ornamental decoration from simple, quiet tinting to the most elaborate and ornate display of coloring, gilding and bronzing, giving abundant scope for display of taste and talent to the most gifted decorative artists.

PLUMBING IN SMALL BUILDINGS.—Many people are prejudiced against placing a water-closet in the house, presuming that foul odors and danger to health will follow shortly after its introduction. A careful estimate shows that in an average house, built ten feet back from the street line, two stories high, the cost of putting in a soil pipe and house sewer will be about $60; a kitchen sink with waste, trap and vent, $15; water closet, tank, vent pipes, etc., $40; carpenter work, joiner work, plastering, painting, etc., $10; total, $125. A bath-tub and wash-bowl, although desirable, are not necessary; they can be added at an additional cost of about $40. In any building worth $1000 an expenditure of $125 for putting in plumbing fixtures is not extravagant when we consider the danger to health avoided in winter, by the use of water-closets within a building, instead of outside privies, and in summer the improved sanitary condition of the premises, especially of the back yard and the rooms overlooking it. The floor space required in a building for a water-closet compartment need not exceed three feet by four feet, but that compartment should be well lighted and ventilated.—*Ex.*

A WATER TELEPHONE has been recently patented in England, an apparatus employed for the collection of sounds transmitted though water, particularly between ships, but some difficulty is experienced in properly recording the sounds on account of the instrument being affected by other causes, such as the movement of the ship. This defect has now been remedied by constructing the apparatus so that any pressure caused by the increased density of the water has no effect upon it.

A USEFUL ATTRIBUTE OF PAPER not generally known is for preserving ice in a pitcher of water. Fill the pitcher with ice and water, and set it on the center of a piece of paper; then gather the paper up together at the top and place the ends tightly together, placing a strong rubber band around the coil to hold it close, so as to exclude the air. A pitcher of ice-water treated in this manner has been known to stand over night with scarcely a perceptible melting of the ice.

THE HOUSE ARCHITECTURE of to-day is, in too many instances, like too many other things of the time—cheap and showy. The dwelling the persuasive house agents seek to palm off on the innocent householder of small means has a tower, bay windows, gingerbread chimneys and curlyone walls, but no cellar. Just the most important part, next to a good kitchen, the plain, convenient, old-fashioned cellar, with solid stone walls, keeping the house cool in summer and warm in winter, is left off. It costs too much. So, when you buy a house, be sure that it has a tower, a galvanized, painted sheet-iron affair, like a tin pan turned bottom upward. Oh, yes! Let the cellar go, but do not omit the tower or the cast-iron monkeys around the railing.

A DERRICK used by a shipping company at Hamburg can pick up a ten-wheeled locomotive with perfect ease.

USEFUL INFORMATION.

How to Trim a Lamp Wick.

If a lamp wick is trimmed by shears, cutting it across just below the charred part, one end will almost certainly be left higher than the other. In such a case the wick cannot be turned up enough to give much light, because the higher end of it will begin to smoke before the remainder of it gives out one-quarter of the light which it should. If the wick is cut straight across, the flame will be irregular. This kind of a flame is caused by inequalities of combustion at the sides and ends of the wick. To cut a wick exactly square across is almost impossible, even if it were best; and a flame with a low center and a tall, flaring, smoky horn on each end is a bad flame. It is bad for the lamp chimneys and for the eyes. No lamp which has such a flame is properly trimmed. If one tries to avoid the horned flame by rounding off the ends of the wick, an imperfect flame will result. This flame may not crack chimneys, but it will give out but little light. It shows an honest attempt to trim the lamp properly, but an unsuccessful one. To secure a good flame, the lamp-trimmer should be instructed to turn the wick up until about one-eighth of an inch projects above the brass sheath. Next, let him take off the charred portion. Let this be done with the forefinger and thumb.

Cutting with shears, besides the mischiefs already set forth, will take off more than is necessary. Rubbing off the charred portion with the back of a knife, or a blunt edge of any kind, will generally leave fibers, which will cause an uneven light. With the finger and thumb just enough can be taken off, and taken off smoothly. All that will not easily break off is good, sound wick, no matter how black it may be. After pinching off the burned portion of the wick, take just as little off the corners of it as a sharp pair of shears will take hold of and cut. There is always more danger that too much will be taken off than too little. But if just the right quantity is removed, and the cuts on the two corners are made at the same angle, the lamps will give out a broad, white flame. To trim a new wick, turn the wick down until the loose and unraveled end projects from the brass sheath, and light it before the oil fills it. It will quickly burn down to the sheath, leaving a straight edge, and can then be trimmed as directed above. The end can as well be burned down to the sheath before the wick is put into the oil.

MUSTARD OIL AS A LUBRICANT.—Mustard oil has of late been given some attention as a lubricant—in fact it is reported to have been successfully used for some time in Germany for lubricating purposes, being manufactured at Ilversgehofen, near Erfurt. It is said not to be susceptible to cold until a temperature of from nine to ten degrees centigrade below zero is reached, and besides does not easily become rancid or form fatty acids which would attack metal. Its lubricating value, moreover, according to Professor G. Herrman, of Aix-la-Chapelle, is of a relatively high order. No particulars have been yet given as to the cost of the new lubricant, its specific gravity, etc.

HEMP SILK.—Mr. Nayemura Sakuahuro, a druggist of Hikone, in Omi, Japan, has succeeded in converting wild hemp (yaohyo) into a substance possessing all the essential qualities of silk. Nothing is said about the process, but it is asserted that trial of the thread has been made at the first silk-weaving establishment in Kioto and other factories, with excellent results in every case. The plant in question grows on moors and hillsides. Its fiber is said to be strong and glossy, in no wise inferior to silk when properly prepared. Cultivation on an extended scale would present no difficulties.

A CUP OF COFFEE.—Coffee is far more delicious when made with egg than it is without. One egg to a teacupful of ground coffee is about the right proportion for a rich extract, but less than this can be easily used by adding a teacupful of cold water to a well-beaten egg, and using enough of this mixture to thoroughly wet the ground coffee. Beat an egg thoroughly, add two tablespoonfuls of cold milk; pour this mixture into a pint of boiling milk, let scald but not boil. Try this when you have no cream for breakfast coffee.

ENGINEERING NOTES.

Connecting the Mississippi with the Lakes.

The work of connecting the Mississippi with the Great Lakes may now be considered as an enterprise fully determined upon.

The law passed at the last session of the Illinois Legislature, providing for an immense system of drainage for the benefit of Chicago and its environs, and preparing for the building of a great waterway between Lake Michigan and the Mississippi river, has been declared constitutional by the Supreme Court of that State, and will soon begin to take a practical form.

The main plan involves a diversion of the sewage of the city from the Chicago river and Lake Michigan, sending it through the Illinois and Michigan canal, or the Des Plaines, into the Illinois river, with a sufficient flow of water to render it harmless to the health of the districts through which it is to pass. The State authorities, to insure the best results in this and other respects, decided that the sewage outlet must be made also a navigable waterway.

The aggregate cost of the work will be somewhere in the neighborhood of $20,000,000, perhaps more. An annual taxation of some $2,000,000 will be assessed upon the property, to be directly benefited by the improvement. But as it is one of the most wealthy districts in all the Great West, and the benefit to be derived a very important one, no objection will be made to the assessments.

The work is really one of national importance, and there is really no good reason why the National Government should not give material assistance to the enterprise, especially as it will afford a waterway directly into the lakes for the admission thereto of warships, and open up a new commercial waterway for a large region of the Upper Mississippi valley.

The English Channel Tunnel Craze.

The engineers of Europe are doing their best to devise some engineering scheme to connect England with the continent, so as to do away with the fearful craze that, somehow or other, either tunnel or bridge will open up a highway over or through which the armies of Europe may at some unexpected moment pounce upon the now tight little isle, and make it an annex to France or Belgium. The latest plan is that of a French engineer, who proposes to accomplish the work by a union of bridges and tunnel. His scheme borders on the audacious. He proposes to build a pier or viaduct half a mile in length on each side of the channel. These piers are to be connected by a tunnel with continuous rails, the descent from the bridge to the tunnel being effected in a tube by any system serving for steep inclines. The distances from the extremity of the pier to the mouth of the tunnel is to be only 80 or 100 yards. The undertaking is estimated not to cost more than a tunnel. The works will not obstruct the navigation, nor create any International difficulty, for the pillars of the piers are to be 500 yards apart, with a hight of 150 feet. The scheme, M. Varilla says, can be carried out in six years. It meets strategetic difficulties, for the tunnel terminates out at sea on both sides, and if the connection between pier and tunnel were interrupted, the train cannot ascend or descend, for, when the tube is once destroyed, the tunnel is submerged.

All sorts of reasons have been hunted up from time to time to bring the English public to the point of thinking that there must be some way of accomplishing the work without endangering the safety of English soil. There are now three ways proposed from which choice may be made. We are waiting to see what our English cousins will say to the last. Ever since the first Napoleon threatened a war of invasion, the English have looked with suspicion upon any attempt to facilitate communication between the British Isle and the mainland. The commerce of the world requires that some plan should be accepted, and this last seems to be practicable and less expensive than either a tunnel or bridge for the whole distance.

MINING ENGINEERS.—The fifty-seventh meeting of the American Institute of Mining Engineers will be held in the City of New York, beginning Monday evening, September 29, 1890, and continuing on Tuesday and Wednesday of that week. The members of the Iron & Steel Institute of Great Britain, and many other foreigners interested in engineering enterprises generally, will also attend the meeting.

A FLOATING TUNNEL.—James Maxton, a civil engineer, proposes to build a floating railroad tunnel, to be anchored about 60 feet below the surface across the North channel, between Ireland and Scotland, a distance of 20 miles, and between Patrick and Donaghade. The estimated cost is £5,520,000.

TABLE OF CONTENTS.

EDITORIALS.—Academy of Sciences Building, 17. Passing Events; The Silver Compromise Bill; Gold Mining in Nicaragua; Electric Power in Mining; Mines in the Argentine Republic; San Bernardino county, 24. Mono Lake; Gold from Beach Sand; Clean-Up Pan, 25.

ILLUSTRATIONS.—Academy of Sciences Building, 17. Clean-Up Pan; Beach Sand Gold Saving Machine; Tufa Towers near Black Point in Mono Lake, 25.

CORRESPONDENCE.—The Gold Belt of Northern California; The Mines of Eldorado County, 18. San Bernardino County, 19.

MECHANICAL PROGRESS.—American Inventions Abroad; Structural Iron in New England; Possibilities of Invention; A Non-Explosive Boiler; Sugar in Steam Boilers, 22.

SCIENTIFIC PROGRESS.—Recent Discoveries in Magnetism; The Air Brush; The Big Iowa Meteor; Atmospheric Electricity; Cold Air on Tap; Fogs and Orchids; How Powder Scores Gun Bores; Difference in Tide Levels near New York; Miscellaneous, 22.

GOOD HEALTH.—Old and Young Should Not Sleep Together; Mistakes; Surgery of the Lungs; The Office of Iron in the Blood; Colored Spectacles; Something New in Skin Grafting; For Toothache, 23.

THE BUILDER.—Causes of Decay in Stone Buildings; Panelled Iron Ceilings; Plumbing in Small Buildings; Miscellaneous, 23.

USEFUL INFORMATION.—How to Trim a Lamp Wick; Mustard Oil as a Lubricant; Hemp Silk; A Cup of Coffee, 23.

ENGINEERING NOTES.—Connecting the Mississippi with the Lakes; The English Channel Tunnel Craze; Mining Engineers; A Floating Tunnel, 23

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Wyoming, 20-21.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments Dividends, and Bullion Shipments, 28.

MARKET REPORTS.—Local Markets, Eastern Metal Markets, 28.

Passing Events.

The Silver bill reported to the Senate by the "Compromise Committee" is attracting the attention of the silver men and is given elsewhere in this number of the PRESS. A careful study of the situation forces the conviction that the recently expressed views of Hon. Francis G. Newlands on the silver question will be the rallying cry of the himetallists throughout the United States, and that the friends of silver will support at the coming Congressional elections only such as are in favor of placing silver on the same footing as gold.

The molders' strike still continues with little change. A few men desert the foundrymen, but more come from the East to take their places. The foundrymen say they can fill all orders with their present force of molders.

Elsewhere in the PRESS is a brief description of the Dalmatia mill—the first quartz mill in California to be run by electricity. The plant is three miles distant from the point where the power is generated.

THE Marysville *Democrat* says everything is booming at Smartsville now under the influence of the drift mining operations, there being 84 men employed in the Blue Point, 60 in the Wheaton and 40 in the Mooney Flat, making a total of 184, all of whom are paid good wages.

A MARBLE MONUMENT to Padre Junipero Serra, the founder of the California Missions, is to be erected on the beach at Monterey, through the liberality of Mrs. Leland Stanford.

THERE are in Utah 11 smeltere, 6 large stamp-mills and 10 sampling works.

The Silver Compromise Bill.

On last Monday the Conference Committee on the silver bills reported to the Senate a compromise measure. The substitute provides that the Secretary of the Treasury shall purchase from time to time silver bullion to the aggregate amount of 4,500,000 ounces, or so much thereof as may be offered in each month at the market price thereof, not exceeding $1 for 371 25 100 grains of pure silver.

Treasury notes issued in payment will be redeemable in coin, and will be legal tender in payment of all debts, public and private, except where otherwise expressly stipulated in contract, and will be receivable for customs, taxes and all public dues.

Upon demand of the holder of the Treasury notes the Secretary shall, under such regulations as he may prescribe, redeem such notes in gold or silver coin, at his discretion, it being the established policy of the United States to maintain the two metals on a parity with each other upon the present legal ratio or such ratios as may be provided by law. The Secretary of the Treasury shall each month coin 2 000,000 ounces of the silver bullion purchased into standard silver dollars until the first day of July, 1891, and after that time he shall coin out of the silver bullion purchased as much as may be necessary to provide for the redemption of the Treasury notes.

The present law is repealed. The last section provides for covering into the Treasury the fund held for the redemption of the National bank circulation.

The bill is far from satisfactory to himetalists, but it is perhaps the best that can be obtained at this session of Congress. Had provision been made for free coinage after the price of silver advanced to par, then no serious objection could be urged against the bill, but as it is, silver is still treated as a commodity and as such it will be subjected to speculative influences. This, of course, is what Wall Street and the "gold bugs" in general at the East wish, for they can get higher rates of interest, besides speculate to a much better advantage, but to the country at large it is ruinous, for there are too many industries whose prosperity is dependent upon silver—the higher it advances in price, the greater the benefit that will be secured.

Gold Mining in Nicaragua.

A new mining law has recently been adopted by the Government of Nicaragua, in some respects modifying the *codiga de mineria*, under the provisions of which all the mining operations of the Republic have been conducted. A noticeable feature of these laws will be found embraced in Article 2 and which requires a foreign resident who wishes to enter or denounce mining lands in the new district of Prinzapolka on the Mosquito Reservation, to renounce in his petition his foreign status and all right to appeal to his home government in case of damages to his person or property.

The reason assigned by the Government for the adoption of these new rules for entering mines is the discovery of gold-bearing banks and streams above the river Prinzapolka, which discharges into the Caribbean sea about 60 miles north of Bluefields, its course from the mountains being in a southwesterly direction and passing through the Mosquito Reservation. The discovery was made at the end of 1888, about 150 or 200 miles from the Caribbean coast, and the fields are not to be reached except by tedious travel in canoes and on the backs of Indians. The section was reported on by a Government expert and a new district was created. It is to this district the new laws apply.

Electric Power in Mining.

In another column our correspondent in El Dorado county describes briefly the electric plant for power at the Dalmatia mill, the first complete one in the State. The generator, operated by a Pelton water-wheel, is three miles (not one mile, as stated) from the mill, and from a pulley on the motor at the mill, a belt carries the power direct to the main shaft, driving the rock-breakers, Huntington roller mills and stamps. Another 20-stamp mill is to be connected with the same power. A three-nozzle Pelton wheel runs also a complete electric light plant, with which the mill is lighted.

There has been more or less talk about operating mining plants by electricity in California, but this is the first complete electric power outfit applied to mining in the State. There are many other places where water power is within a reasonable distance of the mine or mill, where the same system could be applied with great advantage. No difficulty is found in conveying the electric power the three miles from the source. The machinery is as easily controlled as if run by steam or direct water power. It will repay all those who have available water power within a few miles of their mines, to go personally and see the Dalmatia mill, so as to inspect this successful electric power plant.

Mines in the Argentine Republic.

In regard to the mines and mining of the Argentine Republic, it is the same old story—no one has yet discovered the bonanza. With all the outlay of capital and machinery which has been going on for the past ten years, the returns are yet of the most meager description. The gold from Terra del Fuego was all taken from the neighborhood of San Sebastian bay, on the east coast, and Mr. Julio Popper, the mining engineer in charge, is sanguine that a big find of dust will be yet made from the diggings along the Outler river or Carman Silver Mountains. Yet the whole country only produced $75,000 in gold in 1888, and $32,755 in the first nine months of last year. It produced, however, bismuth, copper, tin, silver, lead and borax. Its borax was worth $679,024 in 1888 and $547,070 in the first nine months of 1889. The total value of all mineral products for 1888 was $1,526,057, and for the first nine months of 1889 $1,399,295.

Hundreds of companies have been organized to search for gold, but they need coal more than gold down there. The U. S. Consul says that if some real "live Yankees" would go to Buenos Ayres and set up in the coal business, there would be more money in it than in mining. All the railways and industries of the Republic are at present dependent on foreign coal.

Those Americans in a position to speak say the country is no place for emigrants from the United States, except for capitalists who propose to engage in commercial pursuits or the business of sheep or cattle farming on a large scale. The public lands are sold at auction by the square league, and it is only moneyed men or speculators who can afford to buy them in.

San Bernardino County.

In this issue we present to our readers the first number of a series of articles on the resources of San Bernardino county, from the pen and observations of J. H. Crossman, who visited that county last year in the interest of the California State Mining Bureau, as assistant to William Irelan, Jr., our State Mineralogist.

Mr. Crossman has also in preparation a much-needed and reliable map of San Bernardino county, with profile and sections of the desert regions. The map will be published in the MINING AND SCIENTIFIC PRESS as soon as completed. It will be comprehensive, as well as from notes taken on the field, showing the mineral districts and mines, proposed railroad routes, mountain ranges and lines of volcanic disturbance, etc. In fact so far as practicable, the geographical, topographical and mineralogical features of the almost unknown desert region will be shown on a scale sufficiently large to be of service to the prospector and miner. Township and section lines will be shown and many errors corrected that exist in all maps in use at date, even those issued by the U. S. Government. Survey lines having been run since 1856, when the desert region was triangulated by a few corners stuck in the valley desert region, but no section lines run in the mountain ranges.

The descriptive matter in Mr. Crossman's articles will give the general features of the country and enter into many details concerning its mineral and industrial resources.

"INDUSTRIAL EDUCATOR."—At the meeting of the Oakland Board of Education Tuesday evening, Ronald B. Gleason of Oamhridge, Mass., was elected to the position of Industrial Educator, a position recently created in the public schools of Oakland. The salary was fixed at $1800 per annum.

Academy of Sciences Building.

(*Concluded from page 17.*)

end fireproof casements, lighted by a well on the west side, covered by a glass skylight at the top of the shaft. A large light-well over the staircase and hallway affords abundant light to both on every story. The fire-hose closets are arranged on each floor near the elevator-shaft, and the sanitary arrangements are also complete on all seven stories.

From this description it will be seen that the front building is a first-class store and office structure, of which there are many similar ones in the city. The rear building is of more interest to the majority, and will be a museum and scientific repository equaled by few in this country. While the front structure is to be fire-resisting, the rear one is absolutely fireproof in the fullest meaning of the word. There is no wood whatever used in its construction except for the mere floor coverings in the upper part of the building. The ground floor is devoted to an assembly hall, the second to a museum, and the four upper floors are merely galleries running round all four walls and connected by an iron staircase from the second story up.

The approach to the academy is made a specially attractive feature. At the end of the main hallway a bold arch resting on double columns of white marble opens on to a low flight of white marble steps rising to a spacious landing, at the end of which a shrinelike niche forms a fitting receptacle for a bust or medallion of James Lick, with a record of the bequest beneath it. The balustrade, all of marble, is richly carved. It is bold in design, in keeping with the Romanesque exterior, and is one of the handsomest staircases in the country. From the landing another short staircase rises on the left to a second landing, opening on the museum floor, all the stairs being of marble. The space occupied by these stairs and landing is canopied by a beautifully finished glass roof under the dividing light-well, behind the partition wall of the buildings.

The lighting of this rear building has received special attention—on the Pioneer place, or east side, a frontage of 50 feet; on the west side, a light-well 50 feet long, corresponding with that frontage; on the north the well 80 feet long; on the south the Stevenson-street frontage, and the skylight on the top of the building 70 feet long all contribute to this end. The galleries, corridors and passages will thus be flooded with light at all times.

Passing round the foot of the staircase on the ground floor and to the right, ingress is afforded to a broad marble corridor which encircles the assembly hall on three sides. This hall will stand of itself inside the building and have a sloping amphitheater of seats, with a raised platform at the south end. The roof of the hall, which forms the museum floor, is to be Romanesque, as well as all of the decorations. Heavy columns and boldly projecting beams forming deep panels in the ceiling, fireproof walls lighted by stained-glass side-windows looking out on the corridors, and doors handsomely carved, all contribute to make the temple of science strikingly handsome.

On the same floor at the left of the hall, and along the slanting wall of the Pioneer building, there will be a good sized reception-room for smaller meetings, and behind it, as well as along the Stevenson-street side, space for toilet-rooms is to be provided.

The museum and galleries forming the five upper stories need no special description, the chief point in their design being their fitness for the uses to which they are to be put. The galleries are to be 20 feet wide all round, carried on columns continued from the lowest story through to the roof. The estimated cost of the entire building, front and rear, is $280,000.

It is a matter of pride for San Francisco, one of the youngest of the large cities of the United States, to have so fine a building devoted to science. With the money that will come in due time from the Lick estate and the income afforded by the store-portion of the building, the California Academy of Sciences will be one of the wealthiest private institutions of the kind in the Union. Its members have passed through many struggles of a financial nature since its organization in 1853, but on the completion of the building the institution will be on a footing which will greatly enlarge its usefulness.

Mono Lake.

Lake Mono is situated in east-central California, within a few miles of the California-Nevada border. The lake is 6380 feet above sea level. The Mono basin is remarkable for its diversity of topography, its varied and striking contrasts of scenery, its wide range of climate and corresponding variations of flora. Besides these more obvious characteristics, the basin has a varied geological history, the later chapters of which are of fascinating interest and can be read with unusual facility.

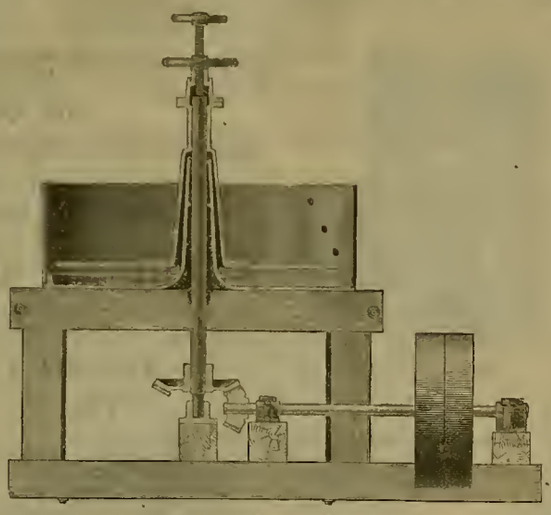
The highest peaks that overshadow the lake rise more than 6000 feet above its level. Over the entire area of the basin no running water can be found during the greater part of the year, and the region is consequently silent and lifeless. Near the shore of the lake are low hills with castellated summits which at once attract the attention of the geologist by the peculiarities of their forms. These are tufa crags, mainly composed of calcium carbonate which was deposited from the waters of the lake when it stood much higher than now. There are three varieties of this tufa, tubular masses being sometimes formed, that appear to have been precipitated from springs.

The lake is rudely circular in outline, and, including its islands, has an area of 87 miles. The average depth is about 62 feet, and the greatest 152 feet of water. The entire bottom is of soft black mud. The most remarkable features of the lake are the absence of an outlet and the strongly alkaline condition of its water. The lake derives the principal portion of its water supply from the creeks that descend the slope of the Sierra, and supplementing this surface drainage are a number of springs, many of them warm ones.

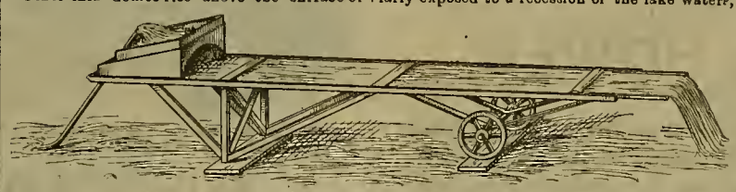
At the western extremity of the lake are several sublacustral springs. Two of special interest rise at the base of tufa crags 20 or 30 yards from the lake shore. At the present time they are not depositing mineral matter though the tufa about them was evidently deposited by them. The positions of the springs rising in the lake near Black Point, are indicated in calm weather by the eddies on the lake surface. On rowing over these submerged springs it is seen that some of them rise from the tops of tufa crags which are covered by 10 or 12 feet of water. These crags are of the same character as those on the shore and were formed by the deposition of calcium carbonate from the incoming waters. The submerged towers from which these springs issue are in some instances eight and ten feet in diameter and 20 or 30 feet high. They are clustered in groups in the same manner as the tufa towers and castle-like masses which have been left exposed by the receding waters of the lake.

Unlike the masses that have been exposed to the atmosphere, their forms are unbroken. The upward rush of fresh water from the orifices in the summits of these sublacustral towers is often strong enough to deflect a boat when allowed to float over them.

Other tufa domes rise above the surface of the lake near the shore and add an interesting and rural feature to the scenery. A group of these domes seen from the shore near Black Point, looking toward Mt. Warren, is shown in the accompanying engraving which we reproduce from "The Quarternary History of Mono Valley," by Israel C. Russel, published in the U. S. Geological Survey Report. These domes rise in water that is 10 or 12 feet deep to a hight about 12 feet above the surface. Many of them are vase-shaped, as shown in the illustration, being smallest at the water's surface, and nearly circular in outline. The more symmetrical ones appear not unlike huge specimens of the sponge, known as "Neptune's Cup." The tops of several are hollowed out so as to form basins, and in a few instances these depressions are filled with clear, fresh water that rises through the porous and tubular tufa comprising the submerged shaft of the structure. These are typical specimens of sublacustral spring deposits which have been left particularly exposed to a recession of the lake waters, but are still points of discharge for the springs that built them. The water of one of these natural fountains rising in a lake whose water is utterly undrinkable is of exceptional purity. The only other instance where fresh-water springs have built up islands in a saline lake is in Lake Texcoco, Mexico.



CLEAN-UP PAN FOR WORKING AMALGAM.



BEACH BLACK-SAND GOLD SAVING MACHINE.

TUFA TOWERS NEAR BLACK POINT IN MONO LAKE.

A POCKET.—A *News* special from Tincup, Col., gives an account of a wonderful discovery of gold ore. The find is six miles from Tincup, on Cross mountain, and is owned by McCormick & Lewis. A good many men are going to the camp, but ore reported as assaying $20,000 to the ton is not apt to make a permanent camp. They have probably struck a pocket like many of the Tuolumne county mines show in this State. These people have, however, figured up a yield into the billions, figuring on the whole ledge 1000 feet deep and 1500 feet long as being almost a mass of gold.

Gold From Beach-Sand.

One of the forms of machines used in washing the auriferous sands of the ocean beaches of Humboldt and Del Norte counties in this State, is shown herewith. The machine is portable, being moved about on wheels from place to place on the beach. Water from a reservoir at a greater elevation, is supplied by a hose, a supply of from three to four miners' inches being required. The water flows from the hose into the hopper, which is provided with a perforated iron bottom. The black sand as collected from the beach is shoveled into the hopper with the water.

The table or sluice-box, 18 feet long by 18 inches wide, is set to a grade of six inches, and is covered with silver-plated amalgamated plates. Cross riffles one inch in hight are put on this to check the flow.

This appliance is quite simple in construction and operation, and being readily moved about, is found to be effective. Of course a gravity water supply is necessary, so it can not be used on all beaches. At the Gold Bluffs of the Northern California coast the black sands are washed in these machines, but care must be taken as to the flow of water, as the gold is very fine and there is very little difference in its specific gravity and that of the black sand in which it is found.

Clean-up Pan.

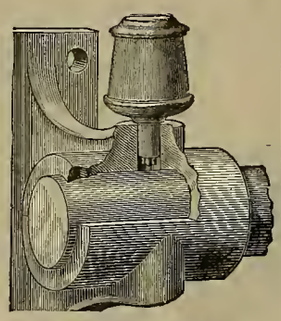
The accompanying cut gives a sectional view of a clean-up pan for quartz mills. In these pans, the amalgam is worked with additional quicksilver and the waste matter washed off before retorting. Wooden shoes are attached to the arms and they are adjusted by means of the band wheels on top of the driving spindle to bear on the bottom of the pan or not as desired, the motion being communicated through the bevel gear underneath the spindle. The Fulton Iron Works of this city also build these pans heavier for grinding or they may be used in prospecting, and also for brightening small quantities of concentrates from blankets and sluices that they may be taken up by the quicksilver.

CHINESE GOLD MINING.—Two of the Chinese cabin passengers on the Gaelic Wednesday were Tong Sing Kow and Wong Leong, who represent a Chinese mining syndicate and are here for the purpose of buying machinery to work gold mines in the Sangtang mountains. Kow says the mines are very rich, assaying $18 of gold to the ton and $8 of silver. He says that he will purchase several hundreds of thousands of dollars worth of machinery, and will buy it in this city if the strike does not prevent his having his orders filled.

FOR the coming Mechanics' Fair, many applications for space are being made. The rules and premium lists have just been distributed and have served as a great incentive to intending exhibitors, and applications are coming in freely. Owing to the fact that the Native Sons have secured the pavilion for their celebration of September 9th, the fair will not open until the 18th of that month.

A SHIPMENT of 13 bars of bullion, valued at $56,605.83, has been made from the Con. Cal. and Virginia mine to the Carson Mint. This is the final shipment of June account, making a total for the month of $179,255.07.

ALBANY
Lubricating Compound and Cups.



1868.

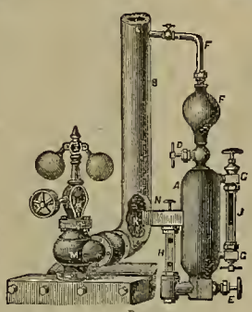
Manufacture commenced a Albany, New York.

1876.

Introduced by us on Pacific Coast.

1889.

Cheap imitations having had time to show that they are the most expensive in the end, the Sales of the Genuine Albany Compound are Larger than ever before.



England, Belgium, France,

And other Foreign Countries are now Large Consumers.

We are also Sole Agents for the

Albany Cylinder Oils,

Albany Spindle Oils, Etc.

FOR SALE ONLY BY

TATUM & BOWEN,

Sole Agents for the Pacific Coast,

Dealers in Improved Woodworking Machinery,

Sawmill Machinery, Engines, Boilers, Ironworking Machinery, Supplies, Etc.

Sole Agents for Hoe Chisel-Tooth Saw, Gardner Governor, Schultz Leather Belting, Etc.

34 AND 36 FREMONT STREET, SAN FRANCISCO.
85 FRONT STREET, PORTLAND, OR.

CABLE-ROAD
REFRIGERATING } MACHINERY.

Special Machinery to Order.

AERIAL WIRE ROPEWAYS.

(Vulcan Patent System)

SINGLE, ENDLESS TRAVELING ROPE.

Elevated on Wooden Posts, from 150 to 2000 feet apart, conveying Buckets of Ore, Coal, Wood, etc.

No Possibility of Load Slipping.

Cheapest Form of Transportation.

No road needed; can be run vertically. No power needed if angle of descent be more than 8 degrees.

CAN SPAN GULCHES 2000 FEET WIDE.

Day's Improved Quartz Stamp Mill.

This Mill is designed for the Prospector, the Assayer and Sampler of Gold and Silver-bearing rock. It is a perfect mill, built entirely of metals, and of the best mechanical construction; will amalgamate perfectly in the battery or on plates. It strikes a sharp, heavy blow with a light stamp. Shipping weight, 225 lbs. Price $75. Address

JAMES DAY,
ATLAS IRON WORKS, Cor. Napa and Louisiana Streets, Potrero, SAN FRANCISCO, CAL.

N. B.—CHAPPARELL, Butte Co., Cal., Nov. 10, 1889.—Mr. Jas. Day, Chico: The little mill is a daisy; it comes up to all expectations; it works perfect in all respects. Yours truly,
WALKER, REESE & Co.

FOR SALE—CHEAPEST OF ALL!

TWENTY-STAMP MILL,

Complete Ore Feeders, Plates and Power, One Double Hoist Cable and Buckets.

Everything in first-class condition. Terms cash. Must sell quick. Address

EUGENE KNAPP, Columbia, Tuolumne Co., Cal.

THE RUSSELL PROCESS.

THE RUSSELL PROCESS CO.,
Park City, Utah.

L. C. MARSHUTZ T. G. CANTRELL.

NATIONAL IRON WORKS

N. W. Corner Main and Howard Sts., San Francisco,

—MANUFACTURERS OF—

Stationary and Compound Engines, Flour, Sugar, Saw and Quartz Mill Machinery.

AMALGAMATING MACHINES. CASTINGS AND FORGINGS Of Every Description

ALL WORK TESTED AND GUARANTEED.

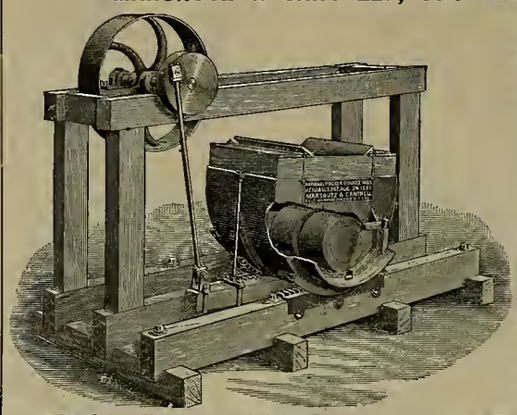
IMPROVED PORTABLE HOISTING ENGINES.

NATIONAL ROCKER QUARTZ MILL.

KENDALL'S PATENT, AUGUST 24, 1886.

CAPACITY, 12 Tons in 24 Hours. 3 H. P.

MARSHUTZ & CANTRELL, Sole Manufacturers.



The Patentee and Manufacturers cordially invite miners to critically examine and pass judgment upon this improved system of milling and amalgamating ores in the following particulars:

1. The cost is less than one-half of stamps of same capacity.
2. The freight to mine is less than one-half of stamps.
3. The cost of erecting is less than one-fourth of stamps.
4. The power to drive it is less than one-half of stamps.
5. The wear is less than one-quarter of stamps.
6. There is no wear except on shoes and dies.
7. In point of amalgamation it is superior to any other machine in use.
8. In its simplicity of construction.

We challenge competition with Stamps, Ball Pulverizers or and other ore crushing machines now before the public.

☞Send for Circulars and Price List. MARSHUTZ & CANTRELL.

FRISBEE-LUCOP MILL CO.,

—MANUFACTURERS OF—

Centrifugal Roller Steel Mills,

FOR PULVERIZING ORES, WET OR DRY,

For Amalgamation or Concentration, and for Manufacture of Cement, Fertilizers, Paint, and all other purposes for which grinding or pulverizing is required.

Send for Catalogue and Price List to

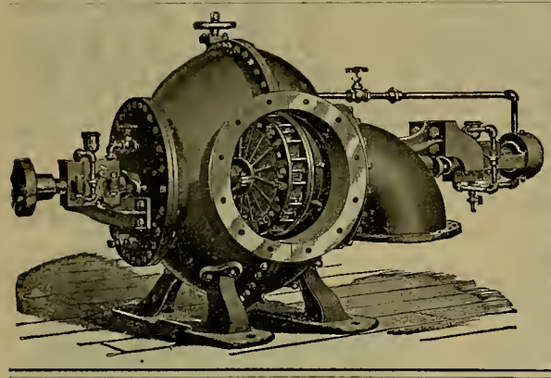
SOLE WESTERN AGENTS FOR TYLER WIRE WORKS DOUBLE CRIMPED MINING CLOTHS.



JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.

Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.

Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers.

And Upward.
Rooms with or without Board,
Free Coach to the House
J. POOLEY.

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, July 10, 1890.

Now that the midsummer bolidays are past and harvest work is nearly over, general trade is expected to sbow a decided improvement.

The money market is easy for tbe season of the year, and everything now points to its continuance. The fruit crop being marketed at higb figures, is throwing large sums of money into circulation. The wool clip is nearly all placed at satisfactory prices; and it now looks as if tbe cereal crops will be marketed at much better general average prices than were obtained last year.

Judging from the best obtainable statistical and other advices regarding wheat and barley, tbe average prices for the two cereals this season, over tbat of 1889-90 will he fully 25 per cent, and may go as high as 35 per cent.

The steamer City of Rio Janeiro, wbich left here for Hong Kong Tuesday, took out the following treasure: Mexican dollars, $80,233; gold coin, $14,895; gold dust, $659.

MEXICAN DOLLARS—The advancing markets for silver with the outlook favorable for still bigher prices causes strong holding of Mexican dollars. The market is quotable at 83@84¼cts.

SILVER—Tbe New York and London markets have steadily appreciated since the bolidays. The strong and bigher markets are due to the Senate and House Conference Committee on the silver bills having come to an agreement (in outline of the joint bill is given elsewhere) and reported the result. This bill, while not giving entire satisfaction owing to its still treating silver as a commodity, is considered to he as favorable as can be expected with the Administration opposed to the free coinage of silver. It is much better than many were led to hope for when tbey found out how strong tbe opposition was to silver. Bimetallists botb in and out of Congress deserve tbe greatest credit for the generalship displayed in presenting and prosecuting their favored cause. Under the discussion which it naturally produced, bimetallists proved more than a match for monometallists. This was due not only to their energy and ability, but also to their cause being founded on right and justice.

It is confidently claimed by those in position to know that tbe next Congress will pass a free coinage bill. This opinion is based on the fact that candidates running for Congress tbis fall will be pledged to vote in its favor, and those who refuse to be so pledged will undoubtedly meet with defeat. With free coinage assured in the near future, the price of silver ought to advance, but in the meantime it is likely that it will fluctuate.

New York telegrams came through to-day quoting silver in that market at $1.06. In our market the Mint has not resumed purchasing, but will do so on next Monday, when correct quotations can be given.

QUICKSILVER—Receipts the past week aggregate 168 flasks. The coast demand continues free, with a strong market ruling, both at home and abroad.

LIME—Receipts tbe past week aggregate 5052 bbls. Tbe demand is good, but not up to what it was at this time last year.

BORAX—Receipts the past week aggregate 227 ctls. The market is steady at unchanged quotations. The demand for Eastern shipment is lully up to wbat it was at tbis time last year.

LEAD—The market has held steady. Eastern advices report the market quiet with the tendency to more ease.

TIN—The market for both pig and plate is firm. The demand shows signs of falling off, which is natural, as the canning season draws to a close. New York advices report a strong spot market, hut lower for futures. English advices report that bear raids caused lower prices, but at the close a steadier tone appeared to have set in. Imports the past week aggregate 27,034 lbs. ingot from Australia, and 28,332 boxes plate from Liverpool. The exports by sea aggregate 34 000 lbs. plate to Victoria.

COPPER—Exports by sea the past week aggregate 24,729 lbs. copper matte to Liverpool. Our market continues very strong. Late Eastern mail advices continue to report strong statistical markets with Lake held at 17c, Arizona ingot at 15½, and 14¾@15c for common casting. *Iron Age* cablegrams from London under date of July 2d report as follows: "Demand for home consumption continues good, as also that from India, and statistics continue favorable, Visible supplies have decreased 9500 tons during the month."

IRON—Imports the past week aggregate 330 tons pig from Irondale and 100 ton from New York. Eastern mail advices report an easier tone owing to the consumption not being up to expectation. *Iron Age* says that "the position of the Charcoal Iron makers had been weakened somewhat by the cancellation of large orders from the Bessemer Steel people, who are understood to have paid a good bonus to be relieved. This released a much larger furnace capacity for the general trade than bad been anticipated." English cables report a better tone to the London market.

COAL—Imports the past week aggregate as follows: Nanaimo, 5854 tons; Biltimore 1825; Coos Bay, 300; Tacoma, 6786; Departure Bay 6938; Sidney 2416; Newcastle, N. S. W., 3990; Seattle, 1459; overland, 20; total, 29 588 tons. The strike at the Dunsmuir-Wellington mines is still on, and it is feared that unless it is settled soon there will be strikes in the other mines. With winter coming on, many dealers are beginning to express some uneasiness, fearing that with the Wellington mine closed, quite an advance will take place in both Coast and Australian.

Eastern Metal Markets.

By Telegraph.

NEW YORK, July 9.—The following ars the closing prices the past week:

Pereone receiving this paper marked are requested to examine ite contente, terme of enb scription, and give it their own patronage, and, ae far ae practicable, aid in circulating the journal, and making ite valne more widely known to others, and extending ite influence in the canee it faithfully eerves. Subecription rate, $3.00 a year. Extra copiee mailed for 10 cents, if ordered soon enough. If already a snbscriber, please show the paper to others.

Don't Fail to Write.

Should this paper be rseeived by any subscriber who does not want it, *or beyond the time he intends to pay for it*, let bim not fail to write us *direct* to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to ston it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPRR

Van Drake's Experimental Machine Works.

It is of the utmost importance to inventors and experimenters that their models and fine work should be placed in the hands of an experienced and skilled man; one who can readily grasp their ideas and execute them with precision, who can assist them over difficulties when they arise, and who will turn out their work with dispatch and economy.

Mr. A. J. Van Drake's service in this line of business extends over a period of more than 30 years, 20 of which have been passed in this city. Many of the productions of his active brain and cunning handiwork are now in general use, both in the East and on this coast, as he was in earlier years employed in the Bidesburg Arsenal near Philadelphia, and also at the U. S. Mint in this city.

For several years Mr. Van Drake bas been engaged in the manufacture of models, fine machine work, electrical appliances, etc., for which purpose he is amply equipped with a force of skilled assistants supplemented by the most perfect machinery. Among these may be mentioned a Brainard milling machine, with cutters costing over $1500, with other machines and tools of corresponding high grade.

Mr. Van Drake enjoys the confidence of those who have had dealings with him in years past, a feature of particular importance to inventors. His works are located at 203 Fremont street.

Cast Steel Castings and Steel Forgings

UP TO 20,000 LBS. WEIGHT.

True to pattern and superior in strength, toughness and durability to Cast or Wrought Iron in any position or for any service.

GEARINGS, SHOES, DIES, CAMS, TAPPETS, PISTON-HEADS, RAILROAD and MACHINERY CASTINGS of Every Description.

— ALSO —

HOMOGENEOUS STEEL, SOFT and DUCTILE, SUPERIOR TO IRON FOR LOCOMOTIVE AND MARINE FORGINGS.

ALSO Steel Rods, from ¼ to 3 inch diameter and Flats from 1 to 8 inch. Angles, Tees, Channels and other shape Steel Wagon, Buggy, and Truck Tires, Plow Steel; Machinery and Special Shape Steel to size and lengths **STEEL RAILS** from 12 to 45 pounds per yard. ALSO, **Railroad and Merchant Iron,** Rolled Beams, Angle, Channel, and T iron, Bridge and Machine Bolts, Lag Screws, Nuts, Washers, Ship and Boat Spikes; Steamboat Shafts, Cranks, Pistons, Connecting Rods, etc. Car and Locomotive Axles and Frames, and Iron Forgings of all kinds, Iron and Steel Bridge and Roof Work a Specialty.

HIGHEST PRICE PAID FOR SCRAP IRON AND STEEL.

☞ Orders will have prompt attention. Send for Catalogues. Address

TUSTIN'S PULVERIZER.

—MANUFACTURERS OF—

MARINE ENGINES AND BOILERS.—Propeller Engines, either High Pressure or Compound, Stern or Side-wheel Engines.

MINING MACHINERY.—Hoisting Engines and Works, Cages, Ore Buckets, Ore Cars, Pumping Engines and Pumps, Water Buckets, Pump Columns, Air Compressors, Air Receivers, Air Pipes.

MILL MACHINERY.—Batteries for Dry or Wet Crushing, Amalgamating Pans, Settlers, Furnaces, Retorts, Concentrators, Ore Feeders, Rock Breakers, Furnaces for Reducing Ores, Water Jackets, etc.

MISCELLANEOUS MACHINERY.—Flour Mill Machinery, Saw Mill Engines and Boilers, Dredging Machinery, Powder Mill Machinery, Water Wheels.

Tustin's Pulverizer

WORKS ORE WET OR DRY.

DEANE STEAM PUMP.

ENGINES AND BOILERS

OF ALL KINDS,

Either for use on Steamboats or for use on Land.

Water Pipe, Pump or Air Columns, Fish Tanks for Salmon Canneries

OF EVERY DESCRIPTION.

Boiler Repairs Promptly attended to and at very moderate rates.

AGENTS FOR THE PACIFIC COAST FOR THE

Deane Steam Pump.

SPECIALTIES:

Corliss Engines and Tustin Ore Pulverizers.

Agents and Manufacturers of the Llewellyn Feed Water Purifier and Heater.

THE GIANT POWDER COMPANY

Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as

The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,

Of Different Strengths as Required.

NOBEL'S EXPLOSIVE GELATINE," which contains **94 per cent of Nitro-Glycerine,** and **GELATINE-DYNAMITE, Stronger than Dynamite** and even Safer in Handling.

JUDSON POWDER IMPROVED.

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

BANDMANN, NIELSEN & CO.,

CAPS and FUSE for Sale. GENERAL AGENTS, SAN FRANCISCO CAL.

QUARTZ SCREENS

A speciality. Round, slot or burred slot holes. Genuine Russia Iron, Homogeneous Steel, Cast Steel or American planished Iron.

Zinc, Copper or Brass Screens for all purposes. California Perforating Screen Co., 145 & 147 Beale St., S. F.

COAL MINES OF THE WESTERN COAST.

A few copies of this work, the only one ever published treating of Pacific Coast Coal Mining, have been obtained, and are for sale at this office for $2.50 per copy. It was written by W. A. Goodyear, Mining and Civil Engineer, formerly of the California State Geological Survey.

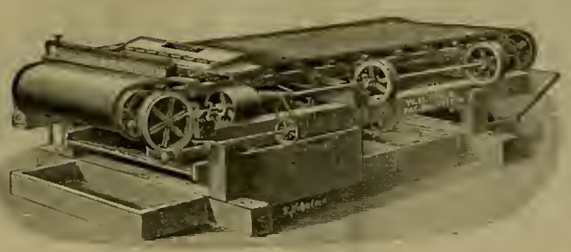
IMPROVED BELT FRUE ORE CONCENTRATOR.

The Best Ore Concentrator in the market, having double the Capacity and doing its work as close as the plain Belt machine, while its concentrations are clean. It is used in a number of Mills, the most notable of which is the Alaska M. & M. Co's Mill, where 24 Improved Belt Frues are taking the Pulp from 120 Stamps, crushing 350 tons per day, and is giving entire satisfaction as against 48 plain Belt Machines, taking the Pulp from the other 120 Stamps.

Price of Improved Belt Frue Vanner, $825, f. o. b.
Price of Plain Belt Frue Vanner, $575, f. o. b.

For Pamphlets, Testimonials and further information apply at office.



Protected by Patents December 22, 1874; September 2, 1879; April 27, 1880; March 22, 1881; February 20, 1883; September 18, 1883; July 24, 1888. Patents applied for.

There are Over 2200 Plain Belt Machines now in Use.

THE MONTANA COMPANY (Limited), LONDON, October 8, 1885.
DEAR SIRS:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Yours truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction that 44 additional Frues and more stamps have been purchased. ADAMS & CARTER.

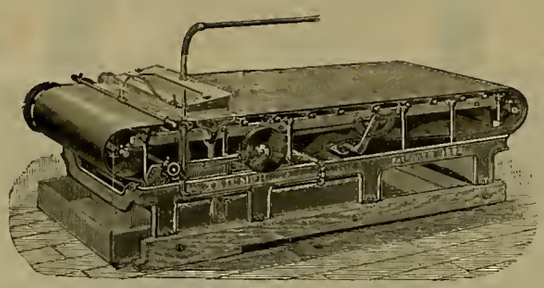
ADAMS & CARTER, Agents FRUE VANNING MACHINE CO., Room 15, No. 132 Market Street, San Francisco, Cal.

"TRIUMPH" ORE CONCENTRATOR WITH IMPROVED RIFFLED BELT.

The competitive trials which have been held between the "Triumph" Ore Concentrators, the "Frue" Vanners and other forms of concentrating devices, do not warrant the assertion that the "Frue" Vanner is the best ore concentrator in the market. The fact that the "Frues" have improved (corrugated) belts does not militate against the superiority of the "Triumphs;" for, when desired, they (the "Triumphs") can be mounted with a superior belt known as the "Blasdel" Riffled.

Price "Triumph" Concentrators, with Improved (Patented) Belt - - - - $650 f. o. b.
Price "Triumph" Concentrators, with Plain Belt - - - - - - - $550 f. o. b.

We are prepared to guarantee the superiority of the "Triumph" over the "Frue" or any other form of Concentrator, for coin if need be. Circulars and testimonial letters furnished on application.



JOSHUA HENDY MACHINE WORKS,
39 to 51 Fremont Street, San Francisco, Cal.

(PATENTED.)

Both the "Triumph" Concentrator and "Blasdel" (riffled) Belt are protected by incontestable letters patent, granted by the Government of the United States.

GRASS VALLEY, NEVADA CO., CAL., Nov. 10, 1885.

Joshua Hendy Machine Works, 39 to 51 Fremont St., S. F., Cal.:

GENTLEMEN—I am pleased to state, in reference to the "Triumph" Ore Concentrators, that four (4) of them were placed in the mill of the Original Empire Mill and Mining Company in April, 1884, and a thorough test made of their practical operation; and their efficiency having been demonstrated, four (4) more were subsequently introduced as the complement of the Twenty (20) Stamp Mill, and the eight (8) have been and are now running with entirely satisfactory results.

At the Ten (10) Stamp Mill of the North Star Mining Company, under my supervision, four (4) are also in successful operation, and from my observation of their practical workings, I am convinced that this form of Concentrators is the equal, if not superior to any other style of Vanners or concentrating devices. DAVID MCKAY, JR.,
(Signed) Sup't North Star and Original Empire Mining Co.

N. B. When the stamping capacity of the two above named mills was increased, more "Triumph" Concentrators were purchased, and twenty-eight (28) are now in constant successful operation.

The Gold Belt of Northern California.

Ancient River Channels and Gravel Deposits.

NUMBER VI.

[Written for the MINING AND SCIENTIFIC PRESS by JAMES F. TALBOTT, Blue Canyon, Placer Co.]

The key of the situation appears to he hnrried here at Bear Valley. We account for the conditions obserued here by the eame line of theory started out on—that the flow of lava was the prime

Cause of the Great Change.

The indications are that the ancient river of the North Fork Dvide ran unobstructed through Bear Valley and down the Shady Run Ridge prior to the commencement of the lava flow; that the lava coming from a source to the eaat etrnck this river where Bear Valley now is. There are extensive lava deposits on the ridge above Emigrant Gap and along the C. P. R. for miles, whereas along on the South Ynba, and for miles beyond to the north, no traces of lava are seen. This shows conclusively that this flow came from some extensive volcano of the Sierras directly east of this point.

This heing the case, the natural result wonld be the accnmulation of a vast hody of water above during the active period of a flow. When, during the intervals of cessation, the pent-up waters would break over and cause heavy floods. The effects of some of these have been described as seen along the O. P. R. R. in the deep cnts above Shady Run. That there was

A High Rim

To the west of Bear Valley is evidenced hy the fact that granite bowlders 10 feet in diameter have been carried from here as far down as Prospect Cut on the railroad. We know these howlders must have come from this section of country for there is no granite wash fonnd outside the rimrock on this ridge. From alternating lava flow and flood the channel down the Shady Run ridge was filled up as far as Bear Valley in ahout the same way, and prohably at the same time that the channel in the Forest Hill ridge was filled np as far as the Brimstone plaine.

To complete the parallel, it is possible that at the same time the diverted waters were cutting ont a channel down the Iowa Hill ridge, nnder the same conditions the water here was outting out the ohannel down the Nevada ridge.

If the eonth hranoh of the North Fork had taken a more southerly conrse above Damascus, and cnt a deep channel through the Brimstone plains into Shirt-tail canyon and then made a sharp hend northward above the plains and out down 200 or 300 feet lower, as the South Ynha ahove Bear Valley, the two divides would he exactly alike from this point down, composed of the two main ridges each. In comparing the Nevada ridge with the Iowa Hill, we account for the disparity in extent and magnitnde from the facts that on the Middle Fork divide the greater hody of water was displaced to the south side into the Middle Fork, leaving less water on the north to out out the Iowa Hill channel; whereas, on the North Fork divide the main hody of water ran down the Nevada ridge, and was afterward displaced to the north into the South Ynha. A detailed description of the Nevada ridge would he a repetition of what has heen gone over in describing the other lava ridges, as all of the conditions are exactly the same. A general outline will be given, and a few prominent points noticed for the purpose of showing the apparent connection with the Shady Run ridge.

The Nevada Ridge.

One peculiarity of the Nevada ridge is that it starts from nothing in Bear Valley, widens and expands in its course westward, till it covers a vaet extent of foothill country, between the South Ynha and Bear river, and is lost in the plains below, and within the gold belt, away back in the early "50's," was noted for having the richeat gold mines in the known world.

In the northeast portion of Bear valley, nnmerous small lakes are seen, along between the reefs of hare bedrock that rise a few feet above the snrface. To the westward those reefs gradually rise a few hundred feet, and are swept bare of all loose material, except here and there a big granite bowlder has heen left on some pinnacle. Above this, these reefs terminate in a narrow, shrupt spur that rises 1000 feet within the limits of a mile. This is the commencement, on the east, of the great Nevada ridge, hetween the South Ynha and Bear river. You can follow along on this high bedrock, to the north, on the bluffs overlooking the South Ynha, about three miles; there you come to the Blue Tent ditch, which ruos in a hedrock tunnel, through a projecting spur, to the north. At no place along here can a veatige of lava be seen.

From this tunnel, the Blue Tent ditch runs in a southerly course, in bedrock, about a mile, then curves around the head of Diamond creek, where it takes a course due west, passing over a deposit of gravel and howldera 100 feet deep, cropping out from underneath several hundred feet of cement and lava. From Diamond creek to Omega, about three miles, the ditch runs over high, sharp hedrock spurs, which project northward to the Yuha river; and to the south, above the ditch, they dip under the lava cap. Here at Omega is

A Deep, Narrow Break

From the ridge (as proved hy shafts and tunnels not more than 400 feet wide). The outlet from this hreak formed the extensive and rich gravel deposit at Omega and Alpha, it being one continnous deposit till Scotchman's creek cut through ahont the middle. Below Omega, the Blue Tent ditch runs over bedrock spurs of the same character as those above, for a few miles westward, where it leaves them and cuts hack into the lava cap, which it follows to the top of the ridge.

The Centennial and other companies have run long hedrock tnnnels along on this side of the ridge, and not one of them is low enongh to hottom the channel. They have invarlably fonnd the bedrock pitching under the lava cap to the south. From all these facts, it is evident there is a high rimrock hetween the lava ridge and the South Yuha, from Blue Tent to Diamond creek, except only where some modern canyon has cnt through, or a break occurred when the channel was heing filled up.

On the South or Bear River Side

Of the ridge, as has heretofore been shown, there is a high rim from the lower end of Bear valley down to Liberty Hill, where there is an extensive hreak from the ridge at Lowell Hill, ahout a mile to the north, forming a gravel deposit which extends south to Liherty Hill, the latter heing a continuation of the deposit from Lowell Hill. A little down the ridge to the west is another hreak at Remington Hill, the outlet of which is into Steep Hollow, below Lowell Hill. Below Remington Hill going west is a rimrock hetween the lava cap and Steep Hollow for a few miles, then you come to where the extensive and rich gravel deposits at Chalk Bluff, Little York and others to the west crop ont from heneath the cement and lava. From this point to the west and north are numerous outlets from the main ridge, which formed a series of gravel deposits extending to Nevada City. This portion of the ridge is composed of long, narrow spurs formed by the modern canyons and creeks ontting hack into those gravel deposits. From all of the facts in regard to the lava cap inside the rimrock, it is evident there is an

Extensive Channel in the Nevada Ridge

And the lava flow from Bear valley, about the middle of the east line of T. 17 N., R. 11 east, extending to near Nevada City, ahout 20 miles to the westward, indicates the course and extent of this channel. From the conditions seen ahout the breaks at Omega and Diamond oreek, the flow that completely hlocked up the upper end of this ohannel must have heen excessive and long continued. At Omega the hreak appears to have heen filled up so suddenly that but a small amount of lava run ont over the gravel heyond the main flow in the ridge. At Diamond oreek the indications are that but a very short time elapsed hetween the hreak and its filling up. At the foot of the steep mountain of lava, great sqnare blocks of cement and lava, imhedded in and covered over with quartz, gravel and howlders, are seen abont the head of the oreek, right under a cliff, 200 feet high, of the same material from which those hlocks were broken off. Overlying and mixed with the quartz gravel here in placea is a peculiar kind of cement, composed of red clay, gravel and lava wash that appears to have heen mixed into a mass of mortar and haked, which gives it in color and consistence the appearance of a soft hrick.

This Same Lava Flow

That hlocked up the hreaks at Omega and Diamond creek, prohably was continnous till it was connected with the flow down Shady Run ridge, therehy forming a complete dam across where Bear Valley now is, and then ceased for all time. After thia, the vaat body of water accumulated ahove haa swept this lava dam away, leaving the lava walls on either aide of the valley pretty much the aame as they are seen to-day. To account for the conrae of the South Yuba here, there mnst have heen a bedrock country all aronnd, higher than thia lava dam, except at some point ahont on a level with it, where the river now rnns, at which point the water broke over at the same time as it did over the dam, thus dividing the pent-up waters and cotting down the Bear river and South Ynha gorgea at the same time. The conditions for erosion being more favorahle to the north, the South Ynha has cut down a few hundred feet lower than Bear river.

On the west, or lower end of Bear Valley is a shaft 80 feet deep, in a mase of howlders and gravel. Between a qnarter and half a mile east of this shaft is a well, sunk 100 feet deep in a sandy loam, free from gravel and howldera. Neither one reached the hed-rock. I can account for

These Remarkable Conditions

In hnt one way. That is, the conrse of the channel heing to the sonth here, the force of a large hody of water falling over the east rim would aweep everything off from that side, and the ontlet down the channel to the south heing blocked up hy the lava flow, the material waa lodged on the west rim wonld account for the gravel and bowlders in the shaft. Afterward, this onrrent of water was displaced into the South Yuha, leaving a small lake of clear water, which was gradually filled up with a sandy loam, snch as is seen on nnmerous bench-like terraces, aronnd the eastern portion of the valley, will acconnt for the material in the well. From all of the foregoing facts it mnst he evident that there is an extensive ohannel in each one of the main ridges of the North Fork divide. How are we to know which one contains the orlginal ancient channel? Of a number, one fact alone is sufficient to decide this point. In the Shady Run ridge the granite deposits are on, or near the top, and don't extend any great distance down. No granite wash has ever been fonnd on the hedrock in the mines on this ridge. On the Nevada ridge, however, extensive granite deposits are fonnd on the hottom, and massive granite bowlders are found on the bedrock in the mines from Diamond creek to Nevada City, which shows conclnsively that the wash down the latter ridge was subsequent to that of the former. This heing tha case, the channel in the Nevada ridge is a modern one, formed under like conditions as the Iowa Hill channel on the Middle Fork divide.

With reference to the viewa heretofore expressed, it may not seem ont of place here to devote some spaoe to the consideration of the

Source of this Great Lava Flow

That marked the end of this epoch. In reviewing the authentic accounts of remarkahle volcanic agencies in modern times, some facts indicate that at no remote time (geological), the volcanoes of the Sierras were active, and pouring their molten lava down the western slope of the steep and rugged mountain section, filling up all the gorges and depressions on its conrse, till it reached the gold helt, where it flowed into and down the ancient rivers "whloh gave it direction" throngh this belt.

There was a tradition of the old Digger Indians on this ooast, that the Great Spirit, on a time got angry at them, turned the snow into oil and set it on fire all along the summit, and hnrned all the rivers up, so that for a long time they oonld get no fish.

Capt. Dutton of U. S. A., Chief of the Bnreau of Volcanic Geology, relates instances in localities not very far from this, where violent erruptions have taken place and sent ont large quantities of lava and ashes, in recent times, in Washington Territory in 1843. In Utah and Sonthern Arizona are evidences of recent violent eruptions. He says: "I have seen lava here in which fragments of Indian pottery was imhedded, showing that the flow was snhsequent to the occupation of the country by Indians. A few years ago, I visited an extinct volcano in Northern California, which was so recent that some of the trees, killed hy the heat from the lava, had not entirely rotted away."

From the preceding facts it is obvious that

No Subsequent Glacial Action

Has taken place, for that would have destroyed all of the evidence hy which the lava flow can be traced to its sonrce. All along the npper side and to the east of the gold helt, on the North and Middle Fork Divides, from near the Sonth Ynha to the Middle Fork and branches to the south, can he seen heavy deposits of lava, between the high hedrock peaks and spurs that rise to the east. In some places the floods and modern canyons have carried some portion of it away, yet leaving evidence sufficient hy which it can he traced directly from the gold helt to the summit of the Sierras, where all traces of it are lost. From the history of volcanlo action in other parts of the world, we are led to the conclusion that the numerons lakes and valleys along the snmmit of the Sierras were once the seething craters of active volcanoes.

A correspondent writing to this paper a few years ago gives an acconnt of his visit to a crater of an extinct volcano in Japan. He says:

"It hardly seems possible that a person with open eyes, in broad daylight, could walk into the crater of a volcano without knowing it, especially when that crater is the object for which he is searching. Whichever way I turned there waa a wall almost perpendicular 1000 feet high; there were one or two breaks or gorgea throngh it. By one of these I had entered without noticing my snrronndings. This waa the crater of Azozan, 15 miles from wall to wall, containing within its walls miles and miles of cultivated fields and nnmerous villages. To think that this once seething firepit should become the scene of snch qniet rural life."

Many instances of remarkable volcanic action in other portions of the world might be given. But why not have something as wonderful in California as in Japan, or any other place? If within the walls of the crater of an extinct volcano in Japan are cultivated fields and villages, why not within the walls of a crater, full as large, of

An Extinct Volcano in California

Have a beautiful sheet of fresh crystal water, high on the mountain-top, surrounded by the grandest mountain scenery on the continent? To think of the impressive beauty and quiet of the surroundings of to-day where naught breaks the stillness but the woodman's ax in the mountain forest, or the merry laugh or song of the tourist and pleasure-seekers as they glide over the placid waters of Lake Tahoe in the little steamer; there, in ages gone by, within those mountain walls the roaring volcano blazed up from thousands of feet beneath this lake, and sent its floods of mud and torrents of boiling lava down the western slope that filled and blocked up the ancient rivers of the Middle and North Fork divides.

San Bernardino County.

Its Mineral and Other Resources.

NUMBER II.

[Written for the PRESS by JAMES H. CROSSMAN.]

A Bedrock Dam.

An important enterprise in the desert regions, and one that is attracting much deserved attention, has been organized and is in process of construction—a submerged dam. The Silver Valley Land & Water Company has in process of construction a hedrock dam to conserve and utilize the subterrnnean waters of the Mojave river that have hitherto in the summer season run to waste by peroolation. Even in the dryest season this river flows a considerable body of water. It appears on the surface and again disappears eight several times before it finally sinks and disappears for the last time in Soda lake. Below Fish Ponds and above Daggett, this eccentric stream takes a plunge and is absorbed hy the pebbles and sands in its bed, to appear again 12 miles distant. This enterprising company has ascertained from repeated tests and measurements that the waters of the river do not enter any subterranean channel or fissure in the hedrock, but is simply absorbed hy the gravel as the sponge absorbs water. The company is building a snbmerged dam to the bedrock 1600 feet in length hy 12 feet in hight, at a point in the hed three miles above Daggett, for the purpose of arresting the snh-surface flow of this water and conveying it by canal and pipes to a point near Daggett, where it can he utilized for power for mills, reduction works and irrigation purposes. Cheap power is a desideratum where fuel is dear. Eighty stampa are in constant operation on the ores of Calico, the motive-power heing steam. The water of this new enterprise will be brought in at a sufficient elevation to utilize it for power. In the Calico mountains there are immense quantities of low-grade ore that could be profitably worked if cheaper power could be procured. It can also be nsed for irrigation purposes, there being large tracts of valuable agricultural land lying helow the point of discharge. The specifications of the work call for three miles of canal, 1400 feet of tunnel, 10,600 feet of pipe and 2000 feet of flnming. The canal will he 20 feet wide at the top, 15 feet on the hottom and four feet deep. Water will he taken out four feet below the surface at an elevation of 2015 feet above the sea and discharged at a hight of 1975 feet. The capacity of the canal is 15,000 miner's inches; grade, 14 feet to the mile. The dam will he hnilt of concrete, cement and atone. Its base will be on the bedrock of granite. Three reservoirs will he hnilt on the line of the canal, each of the capacity of 5 000,000 gallons, in order to conserve the surplus water of the rainy season.

Whenever railroad facilities can be secured this vast mineral country will pour forth her treasures and render the desert regions of San Bearnardino the most productive and prosperous mining region on the Pacific Coast, sustaining a large population of miners, tradesmen and mechanics that must of necessity, at least at present, draw their principal supplies from the fertile valleys that lie sonth of the San Bernardino range. The water so necessary to man's existence that is now only found in pools and springs will he drawn from snhterranean channels through the medium of artesian wells. That nnderground rivers exist there can he no question. Artificial reservoirs will also he constructed where needed and the conditions are suitable.

Timber and Fuel.

Providence, Kingston and Clark mountain ranges contain, at an altitude of ahout 4000 feet, considerable timber that can he utilized, hut below that level the cactus, jnniper, sage-hrush and shelac, together with iron wood and palo verde, form the only fuel available for domestic or power purposes. Fortunately the Gallup mines of New Mexico furnish an excellent quality of coal that is transported over the A. & P. R. R. and delivered at several points on its line where required for power for mille and reduction works at a cost not exceeding $9 per ton. Bnt whenever the Utah Southern shall have extended their lines through this desiccated region coal from the vicinity of Milford, Utah, of superior quality and quite equal for smelting purposes to the celebrated English and Australian, can he laid down at any point on the desert on the line of the road at a price not to exceed $6 per ton. Even $5 would pay the road a good profit. In that event smelting works on an extensive scale (similar to the works of Hills in Colorado) will be located at some central point for the reduction of the immense bodies of base and refractory ores which exist in this section of the country.

Beginning near the Bear and Holcomh Valley section, a helt of timher extends along the mountains almost to Cajon Pass. Red, black and sugar pines grow to a great size; also cedar and lesser trees. This timber helt is 45 miles long hy six miles wide, in which many hundred million feet of timher suitable for lumher are still standing in place. The seven steam sawmills on the mountains last year worked up five million feet. A wagon-road leads down from the mountain forest elevated 5000 feet above the level of the sea, and a narrow-gauge railroad is in process of construction to these regions.

In the desert, however, that lies north of the

San Bernardino range the scarcity of timber is a matter of serious consideration.

Towns.

The desert country north of the San Bernardino range contains the following mining and railroad towns: viz.: Victor, with 100 inhabitants; Oro Grande, 150; Barstow, 150; Daggett, 150; Calico, 400; Ivanpah, 25; Providence, 50; The Needles, 400. Each of these forms a base of supplies for interior mining districts. These towns contain variety stores with large stocks of goods suitable for their trade, hotels, saloons, churches and schoolhouses.

Temperature.

The desert has a mean temperature during the summer months of 90° Fahr., that is, during the month of June, July and August. During the balance of the year the thermometer ranges from 70 to as low as 32°, very seldom, however, falling below the freezing point. The mean annual precipitation is estimated at six inches, but no rain gauge has ever been kept verifying this fact until recently.

Precipitation.

At Mojave Station for six months ending Dec. 15, 1889, rain gauge kept by C. H. Fairchild, agent, shows the annexed figures, the "season" commencing July 1st and ending June 30th following:

1889.	Inches.
July	.00
August 31	.81
September 2	.15
19	.12
October 8	.04
20	.50
21	.68
22	.50
23	1.03
24	.36
November 18	.15
29	.10
30	.20
December 1	.80
2	.50
7	.30
12	.95
13	.80
14	.10
15	1.00
Total	6.52
Dec. 15, 1889 to June 30, 1890	5.95
Total for season	12.47

Mills.

Within the confines of the desert region there are in operation 16 stamp-mills dropping 187 stamps; the cost of these has been about $600,000. The silver bullion annually shipped from Daggett, owing in a measure to the low price of silver, has not been as great for the past two years as formerly, but it is estimated that notwithstanding the depreciation, that the Calico mines together with the bullion returns from Ivanpah, and other localities for the year 1889 amounted in the aggregate to $900 000 in addition. Gold, silver, copper and lead ores that were shipped to Kingman, Denver, and San Francisco equaled $200,000, and that to other points for reduction, $50,000, making a total of $1 150,000. The product of the county of borax, building stone, marble, onyx, lime and bitumen equals $200,000, so the total annual product is $1,350,000.

The City of San Bernardino.

The city of San Bernardino has but recently been incorporated, and, as the county seat of San Bernardino county, is located near the central portion of one of the most beautiful and fertile valleys in our State. The city lies in close proximity to the mountain range of the same name, whose lofty, snow-clad peaks (Grayback and Old Baldy) rear their heads to an elevation of 11,600 feet above the level of the sea. The city proper covers an area of two miles square, and has an elevation of 1075 feet above the level of the sea. It contains an estimated population of 10,000, which, within the past few years, has rapidly increased. Though one of the oldest towns in the State (having been settled by the Josephite Mormons, in the year 1849 and 1850), it is only of late years that it has thrown off its antiquated garb and come to the front as a modern and model city. It shows now all the evidences of prosperity; substantial blocks of buildings of modern architecture, built of marble, granite, stone and brick; first-class hotels with all modern improvements, elevators, electric lights and diamond-bedecked clerks; private residences, surrounded by shrubbery, lawns and ever-blooming flowers; are evidences of refinement and culture. There are four banks in the city with a combined paid-up capital of $718 000. There are two live daily newspapers, and 46 business buildings were erected during the past year, at a cost of $552,300, and 190 residences at a cost of $299,500. A sewer system, with over nine miles of pipe, is now completed. Three miles of artificial stone sidewalk, were laid, and the city otherwise beautified at a cost of $153,000. It contains 7½ miles of street railway, and 16 standard-gauge passenger trains depart from, and as many more arrive at the city daily. Three motor roads enter the city from different directions from the valley lands. Twenty-three trains of human freight reach the heart of the city daily, making it a railroad center and a receiving and distributing point for the surrounding country, particularly from that immense region lying northerly to the Nevada State line, and east to the Colorado river. The climate is unexceptional. Artesian and flowing water abounds, rendering the city a desirable dwelling place. The total assessment roll last year was $4,070 300, with prospects of a heavy and rapid increase the coming year.

Riverside.

Riverside, the garden spot of the county, was founded in 1870. Since that date its population has rapidly increased and now numbers in excess of 10,000 souls. The soil is strictly agricultural in character, though in the immediate vicinity of a mineral district which in the near future will, from the product of its mines, sustain a large and thriving population. I refer to the tin mines of Temescal, on the San Jacinto estate—Rancho de Sobrante — from which Riverside derived its title. On this estate, aside from the tin lodes, there are promising veins of gold, silver and copper of great strength returning high assay values.

The Pinacate gold mining district, geologically in the same porphyritic formation that surrounds the Temescal tin, contains both gold and silver bearing veins undeveloped, owing in a measure to the blighting effects of the litigation that surrounded the title to the whole of the San Jacinto estate. This being now removed, work of development will soon be resumed.

Riverside is famous for its semi-tropical fruits and its vegetables, the soil and clime being especially adapted to their culture. The dryness of the atmosphere insures their maturity to perfection, rendering Riverside the garden spot of the county and the home of the fruits of the semi-tropical clime. There the orange takes precedence as a product. It is celebrated both at home and abroad for its size, delicious flavor and sweetness. The yield of this fruit for the year 1889 amounted in value to $1,000,000. The next in importance is the grape, as the raisins can be cured to perfection in this favored clime. The raisins from this locality are pronounced by competent judges equal to the celebrated imported Malaga. The last year's product of the vine returned a figure in excess of one-half million dollars. But this is not all. Riverside produces peaches and apricots of a delicious flavor, vegetables, grain, hay, etc.

The business portion of the town is modern in construction. The town and suburban residences are models of beauty and denote a high state of prosperity. Railroad connection with the Southern Pacific at Colton by a motor, and the Santa Fe has extended its line to this place. Artesian wells furnish an abundant supply of water for domestic and irrigation purposes.

Redlands.

This place is situated at an elevation of 2000 feet above the level of the sea. It is the third city in importance in San Bernardino county, with a population of 2500. Situated ten miles from the capital and on the line of two transcontinental railroads, it is a baby in age, having been baptized and christened in 1887, but it is a giant in growth, containing over 30 brick business blocks, from two to three stories in hight, with many beautiful residences, opera house, city hall, etc. The fathers of the town were Messrs. E. G. Judson and F. E. Brown, the latter being the originator and projector of the great Bear Valley dam, a masterpiece of engineering skill and workmanship which has already added so largely to the prosperity of the county.

VIEW OF THE SOUTHERN END OF LAKE ZURICH, WITH THE ALPS IN THE DISTANCE.

A Scene on Lake Zurich.

To give our readers a little change from contemplation of Pacific Coast scenery, we present this week an engraving of one of the most beautiful scenes in Europe, a part of the Lake of Zurich and its surrounding mountains. The Lake of Zurich, lying in the northeastern part of Switzerland, is celebrated for its picturesque beauty and its historical interest. The lake is 23 miles long and 2½ miles broad, and it extends from the city of Zurich in a southeasterly direction, nearly filling the valley to the hills on either side, which are the foothills of the Alps. The shores nearly its whole distance on both sides are sprinkled with the finest villa dwellings, owned by people of all nations. The engraving on this page represents the southern part of the lake, with its beautiful islands and shores, and shows the Alps in the distance. On the island upon the right are graves of some of the leading men of the Reformation, for here they took refuge from persecution.

RAILROAD ACCIDENTS.—A Cincinnati man, who has preserved a record of 320 railroad accidents, happening in this country in the past year, finds that only 13 out of the lot occurred from causes beyond human control. The others was due to drunkenness or carelessness.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SUTTER CREEK.—Cor. Amador *Ledger*, July 12: The work of cleaning out the sump of the Wildman mine is completed, and everything will be in readiness for sinking as soon as the pump can be lowered and placed in position. Mr. Higgins, the newly installed foreman, proposes to demonstrate that the entire mill can be run during the sinking operations. The hoisting engine of the old Rose mine is on the ground, and is being put in working order as fast as possible. They expect to strike water in a few days, and will have the hoisting gear ready by that time. The last building on the old Amador Consolidated ground is being taken down.

SUTTER CREEK.—Everything about the Wildman is booming. Supt. Tregloan is making preparations for another sinking of 100 feet, and expects to commence sinking in about a couple of weeks. Experience has taught him the necessity of having the sinking operations keep pace with other developments, and with the Wildman the outlook has steadily improved with increasing depth. A slight rupture occurred at the mine this week. Sam Smitherum, who has been foreman since the reopening of the property, retired from the foremanship. Mr. Tregloan has appointed Sidney Higgins to fill the vacancy. The new foreman is a man of much experience in mining and milling. On Mr. Smitherum's departure for the city, the miners presented him with a gold-headed cane, and he received a serenade by the band. Work has commenced in earnest at the Rose mine. Already four sets of timbers have been put in. The size of the shaft is about 8x4 feet in the clear. Mr. Poundstone expects material to arrive last enough for all requirements. Grading is in progress for the foundations for an engine and hoisting works, which will be pushed to completion as soon as possible. The Lincoln is running along smoothly. The rock that is sent to the mill is said to be of good quality, and indications are favorable for a long run.

Calaveras.

CHLORINE WORKS.—*Prospect*, July 12: Preparations are being made for enlarging the chlorine works at Angels. They will be enlarged to twice their present capacity. A large kiln of brick is in preparation, and will shortly be burnt for the work.

STARTING UP.—The old Bechtel mine at Angels is about to be started again by the Utica Mining Co.—Messrs. Hayward & Hobart. They propose sinking 200 feet farther. It is down nearly 400 feet. John Grange has the contract for the work.

RESIGNATION.—Mr. J. A. Ferson, superintendent of the Union mine at Copperopolis, has resigned his position and will proceed to San Francisco. Mr. Ferson has conducted the affairs of the mine in an able manner, and the company will lose an excellent manager in this gentleman.

El Dorado.

PROSPECTING.—*Mountain Democrat*, July 12: G. A. Richardson and G. W. Kimble have gone to Mount Aukum to rest and to prospect, we hear. Kimble and Charlie Winchell prospected the entire western portion of the county some time ago, and now Kimble and Richardson will prospect the southern portion of the county.

CREVICE.—On Thursday last, while Thos. Evans was at the Stewart claim near Webber creek and sitting down talking about the claim, he noticed a speck of gold in a crevice in the bedrock by his feet. Taking out his knife, he picked the piece out and noticed another piece behind it. He then scraped out a couple of handfuls of dirt from the crevice, which he panned out, and was surprised to find he had between eight and ten dollars in coarse gold, some nuggets being worth from one to two dollars. He unearthed a rich crevice for the owner of the claim, who will at once work the new find. The locality abounds in rich crevices, and a large amount of gold has been taken from them in days gone by, one pocket alone having yielded $1100.

SINKING.—Since taking the water out of the McNulty shaft, Supt. Raw has been sinking on the new shaft that is to be dug in the mine and getting ready for the contract work. The contract has been let on the shaft, and work will now be pushed forward rapidly.

Inyo.

RICH ORE.—*Index*, July 9: We are indebted to Malone & Fuller for a very rich specimen of gold ore from their Yellow Gnat mine at Fish Springs. The vein is small, varying from 4 to 12 inches. They have several tons on the dump and will soon make a run.

CERRO GORDO.—Inyo *Independent*, July 11: The Dunpby-O'Keefe mine at Cerro Gordo is reported to be opening out very well. A large ore body is in sight and shipments are made regularly. A few small veins of ore are reported in the Union mine but no large body yet in sight. The ground looks well as prospecting advances.

Nevada.

MANHATTAN MINE.—Grass Valley *Union*, July 12: The work of improving the road to the Manbattan mine in order to get in material and machinery is practically completed, and work has been started preparatory to the erection of a building over the shaft. It was the intention to open the old drain tunnel, but it has been found so badly caved that it would be cheaper to construct a new one, and for that reason it has been determined for the present to pump all water to the service, which can be easily done with the machinery that will be put up, as there is not a heavy flow of water in the mine.

MANHATTAN MINE.—Grass Valley *Union*, July 2: The Manhattan mine, on Gold Flat, Nevada district, is to start up immediately, the negotiations for a bond on the property, which have been conducted by M. L. Elliott, having been satisfactorily concluded. Mr. Elliott will have charge of the operations of the mine, and will commence work on Saturday. Arrangements have been made for all necessary machinery and pipe secured for the pipeline which is to be laid down to convey water-power. The water supply will be obtained from the South Yuba Co., and the line of pipe will be 1100 feet in length. It is expected that the machinery will all be in place and ready to operate in three weeks, when the shaft will be pumped out and necessary repairs made, after which sinking and drifting will be commenced. The Manhattan is in the slate formation, similar to that of the Grass Valley district, which is regarded as an important factor in favor of successful development.

Placer.

LAST CHANCE MINES.—Placer *Herald*, July 12: Last Chance, owing to its remoteness, attracts but little attention from the mining world, and yet it contains some very good and steady paying properties. The El Dorado mine at the Chance is reported as paying $70 a day to the man, and the Bishop mine is doing nearly or quite as well. The Golden Rifle is thought to be a better mine, even, than either of the above, but the tunnel which has been run into the channel proved to be too high, and another tunnel will have to be run before it can be profitably worked. The Caledonia, owned by David John, Aaron Anson and George Williamson, and worked by them, is yielding good pay at present from a bar outside of the channel.

ELKHORN.—At Deadwood the Elkhorn mine, the Davis mine and the mine of Gould & Dixon are all running, and while none of them are very large enterprises, we are informed that they are all doing pretty well in a modest way.

Plumas.

THE SAVERCOOL MINE.—Greenville *Bulletin*, July 4: On the Fourth, John Taylor, who has a contract at the Savercool mine, showed us a fine specimen of ore taken from a ledge recently developed. The ledge is between six and seven feet wide and is of high grade. The force of miners are drifting ahead. It is the intention of the owners to fit up the mill and start it.

San Diego.

THE HIGH PEAK.—Julian *Sentinel*, July 11: Some months ago C. W. Frost, of Santa Rosa, and A. J. Burnett, of Julian, bonded the High Peak mine, and quietly went about developing it. It had been worked some in the early days with the average success attending developments in all new camps. A few rich pockets on the surface were coyoted out and the claim abandoned to look after other interests. Mr. Burnett being an experienced mining man, he liked the outlook and work was accordingly commenced in an old tunnel that had been run in—long ago. We visited the mine Tuesday and found the upper tunnel in a distance of 125 feet, and followed the ledge, which is well defined and 5½ feet feet in width. On the dump are between 50 and 75 tons of ore that will probably average $20 per ton. We learn that two men can break and place on the dump ten tons of ore in ten hours. The rock is easy to break and but little waste has to be handled. In the lower tunnel that is being run to tap the ledge at a depth of 300 feet the boys are now in some 300 feet and expect to run another 100 feet before the main ledge is reached, although another ledge will be cut in a few feet. A new mill is talked of, and from present indications it will be needed.

Shasta.

A BIG NUGGET.—Redding *Free Press*, July 12: C. H. Behrens of Shasta was in town this week and exhibited one of the finest nuggets of gold it has ever been our pleasure to see. The specimen weighed $312, and was purchased by Mr. Behrens from Cunningham & Drummond, who struck the rich pocket on Rock creek, about 1½ miles from Shasta. With the exception of an ounce of quartz it was a solid chunk of wire twist. The men who struck the pocket from which this nugget was taken have extracted over $3000 and are still at work.

MINING NOTES.—The prospect struck by Bob Small a few miles north of Whiskytown is looking remarkably well. A sale of the claim adjoining the Banghart mine on Mad Mule is now being negotiated. It is likely that Fleming & Bauder will purchase the claim which is owned by Jim Blair and others. According to our northern exchanges the mines on Castle creek are attracting more and more attention. Fleming & Bauder have purchased the Bangbart mine near Whiskytown for $3000, and expect to place a force of men to work in the near future. They seem to be a general air of prosperity prevailing at present all over northern California, especially in the mining business. As we go to press a large sale is in progress of an Old Diggings property. The Niagara has struck a fine body of ore. The Gladstone has stringers of $1000 ore putting into the main ledge in the east drift. The Brown Bear of Deadwood keeps putting out its steady stream of dividends. Myriads of lesser properties in this section of the country are developing good ore bodies, some of which will at some time jump into prominence. Mining middlemen are busy hereabouts securing properties by bond and working interests, but all complain of prices being too high. If they would not play for too high commissions in making sales, a great deal more of capital would find its way into this region. Many disappointments have occurred for want of proper processes of working the ores in this section, and in trying to work base and refractory ores by free milling process. Certain capitalists are now taking advantage of these mistakes, knowing, of course, the free milling part of a mine is limited, and also that all of the great mines of the West have been base and refractory ores. The Ball mine, situated on the opposite side of the mountain from the Black Bear, has $20,000 worth of specimens at the mint, and has shipped $40,000 of tellurium to San Francisco. Eureka and Humboldt capitalists are investing largely in this region, both in quartz and gravel mines. Parties here from Salmon river say the placers are doing fine. Schuner & Co. have taken out $60,000 or $70,000 this spring with 12 men.

THE MINING OUTLOOK.—Redding *Free Press*, July 12: In a conversation with W. H. Fowler, the mining expert who is associated with ex-Governor Perkins and others in an extensive gravel claim in Trinity county, he stated that, in his opinion, Shasta, Trinity and Siskiyou counties have the best mining future before them of any counties in the State. The reason for making such a statement certainly seems conclusive. Compared with other mineral districts, these three counties are yet wild, unexplored and undeveloped. Perhaps what will yet prove the richest mining properties are still undiscovered. The quartz abounding in the three counties named yields a higher per cent per ton than anywhere else in the State, and the Mint receipts will show it. There are mines in this State working quartz yielding from $3 to $7 per ton, and are making it pay. A lead of that character in these three counties, yielding no larger results per ton, would never be developed. The main trouble is, said Mr. Fowler, that the business men of the county have not sufficient confidence in the mines. They lack the courage or the enterprise to encourage the prospectors and the miners. Many a good prospect has been abandoned through lack of a small "grub stake." However, notwithstanding this state of affairs, there are a great number of new mines being developed, and we see mine-owners around us getting rich. Capital is gradually creeping in, and even now some of our best properties are in the hands of foreign capitalists.

BUNKER HILL.—*Courier*, July 12: Parties interested in the extension of the Original Bunker Hill mine, at the mouth of Middle creek, had surveys of their ground made this week. We understand that some of the claims on that once noted and rich-paying mining property will soon be worked again. By the death of some of the principal owners, nearly all claims in the group have lain idle for 20 years; but it is the intention of the heirs to have more work done.

Sierra.

MOUNTAIN MINE.—Sierra *Tribune*, July 12: Contractor George M. Pinney, assisted by Supt. R. B. Harper, is making things hum at the Mountain mine. "That mill must be ready to drop by October 1st," says Contractor Pinney. The wagon-road is being pushed along by contractors Flint and Haggerty, and that together with the flume and ditch is likely to be completed in a couple of weeks. The boarding-house at the mill site was opened several days ago. The superintendent's house is well under way and a short time will suffice to complete it. The mill work is in charge of an experienced hand and everything about the building of that is going like clock work. The tramway man will soon arrive here from New Jersey and begin his work.

MILL RUNNING STEADILY.—At the Garabaldi mine in Gold Valley the mill started up on the 6th instant and is pounding away day and night. It was found necessary to run a tunnel 60 feet through snow on the outside track. At the Young America mill $17,700 was cleaned up as a result of the June run.

Siskiyou.

SCOTT RIVER.—Yreka *Journal*, July 7: The mines in Scott River canyon have shown very rich prospects, and arrangements will soon be made to open them in systematic manner. Pitts and McCarty, who have been prospecting lately without opening their claim to any great extent, brought 20 ounces of gold to Scott River last week, and expect to develop one of the richest bonanzas ever discovered in Siskiyou. The gold is found in a mass of decomposed quartz and gravelly soil, which can be worked like placer mining, but as the owners sink down the claim will probably develop a well-defined quartz ledge. Other parties also have claims in the same locality, which they intend opening during the summer.

CASTLE CREEK.—The Dunsmuir *News* says: Mat Young came down from the mines on Castle creek, bringing a number of rich specimens from his and Mr. Branstetter's claim, which shows up better than anything we have seen come from there before. They have been sinking on the ledge and find it increasing in width and richness as they go down. It is acknowledged now by all who have been up there that these mines are an important discovery. Mr. John Cody also brought down some specimens from a claim owned by him and Mr. Isgrigg, which panned out well in gold.

THE HYDRAULIC mine at Summerville, in the Salmon river district, is turning out exceedingly good this season, with abundant water to keep the giants in operation until September. The hydraulic mines of R. H. Campbell at Quartz Valley, and of the Eastlick Brothers and Wright & Co. at Oro Fino, are all paying handsomely with sufficient water to run the giants until August, being the longest season ever known in the county for working these rich paying and extensive claims.

NEVADA.

Highland District.

NEW OWNERS.—Pioche *Record*, July 7: Several prospects in Highland district have recently changed hands, and the new owners intend to begin work at once. The approaching railroad is the direct cause. The claims of Highland district usually produce ore of too low a grade to bear the expense of shipment to Salt Lake, though the ledges are large and ore abundant. The district was a very prominent one in the early '70's, and will again become so when cheap transportation is afforded.

Washbe District.

SIERRA NEVADA.—Virginia *Chronicle*, July 12: On the 630 level the west crosscut from the southwest drift, 600 feet from the shaft station, is advanced 420 feet, through a clay wall and onward to the west wall, passing through 12 feet of quartz showing low assay value.

UNION CON.—On the 1465 level from the north lateral drift, opposite west crosscut No. 4, east crosscut No. 1 is advanced 564 feet. Continuing in porphyry and clay carrying some water.

MEXICAN.—On the 1465 level, at a point 70 feet south from west crosscut No. 4, west crosscut No. 5 is advanced 229 feet, continuing in porpbyry showing some quartz.

OPHIR.—On the 1300 level the winze at a point 66 feet southwest of the raise is down 66 feet, continuing in low-grade quartz.

CON. CAL. & VIRGINIA.—The 1300 and 1500 levels continue to yield the usual quantity of ore. There has been extracted during the week from all parts of the mine 2767 tons of ore. Shipped to the Morgan mill 1107 tons and 1090 pounds of ore, and to the Eureka 1659 tons and 1280 pounds; battery sample assays showing an average value of $16.75 per ton; 2762 tons milled. Shipped bullion valued at $56,695.83 to the Carson mint.

BEST & BELCHER.—All work on the 1000 and 1200 levels for the past week has been confined to repairs.

SCORPION.—The southwest drift from the 660 level shaft station continues in clay and porphyry.

ANDES.—On the 420 level the north drift from west crosscut No. 2 is in 69 feet; formation quartz, clay and porphyry.

OCCIDENTAL CON.—Continue to extract ore of good quality from the stopes on the 400 and 450 levels. The crosscut from the bottom of the winze below the 550 level is in six feet, showing low-grade quartz.

SAVAGE.—Shipped 400 tons of ore, showing an average value of $22 50 by battery sample assays.

CHOLLAR.—Extracted 404 tons of ore, battery sample assays showing a value of $20.12 per ton.

POTOSI.—Sinking the winze below the 930 level suspended pending the excavation for a station on the 1030 level, preparatory to following the ore vein with lateral drifts.

ALPHA.—The 600 level southwest crosscut is in 51 feet, the face in quartz and clay.

EXCHEQUER.—The 600 level north lateral drift is out 385 feet; face in porphyry and quartz.

CON. NEW YORK.—The north drift from the top of the raise above the 800 level is out 293 feet, the face in porphyry.

IMPERIAL.—The joint Confidence-Challenge 1000 level west crosscut No. 2, is in 194 feet, the face in low-grade quartz. Joint north drift, same level, is in porphyry.

YELLOW JACKET.—Shipped 600 tons of ore showing average assay value of $22 by battery sample assays.

CROWN POINT.—Shipped during the week 625 tons of ore, showing an average value of $15.08 per ton by pulp assays.

CONFIDENCE AND CHALLENGE.—The joint Imperial 1000 level north drift from west crosscut No. 1 is out 135 feet, the face in low-grade quartz.

BELCHER.—The 850 level west crosscut is in 90 feet, quartz and clay showing in the face. Began extracting ore from the 300 level stope July 7.

SEG. BELCHER.—The raise above the 1000 level east crosscut No. 1 is up 162 feet, the top continuing in low-grade quartz.

JUSTICE.—During the week crusbed 167 tons of ore showing a value of $30.44 per ton by battery sample assays.

ALTA.—The ore output this week was 356 tons, showing an average assay value of $21.75 per ton by pulp assays.

OVERMAN.—Shipped 486 tons of ore during the week showing an average value of $22 per ton by battery sample assays.

Eureka District.

ORE SHIPMENTS.—*Sentinel*, July 12: During the week the Eureka and Palisade Railroad Co. shipped 383 tons of ore to the Salt Lake City smelting companies.

PURCHASED ORES.—During the month of June the following shipments of ore were made to the Eureka Con. reduction works for treatment from the mines of the district: From the Lord Byron mine, 109½ tons; Dunderberg, 65¾ tons; Kentuck, 2¾ tons; Ethel, 7 tons; Morning Star 2 tons and Evans 1. From Reveille 10 tons and Mineral Hill 2¾ tons.

Jackrabbit District.

LOW-GRADE ORES.—The low-grade ore bodies opened by the P. C. Co. in the Day mine, and which induced the purchase of the property, continue to improve, and the quantity is simply immense. The same ore showing made by previous owners, and under the disadvantages to which they were subject, would have created but little, if any, comment, as the ore is of too low a grade to justify mining and working alone. Now, however, it is mined and used at the furnace here mainly as a flux and justifies extraction for that purpose. The present proposed terminus of the Pioche branch of the coming railroad will be in the valley some 10 or 12 miles from the mine, all down hill, and the road continued that distance up the valley on the line as now surveyed would bring it within two miles of the property. It is not unlikely that this will occur, Mr. S. V. White having expressed himself to that effect when here recently. In that event, the Day mine with the present showing, though now valuable, would easily become worth a quarter of a million.

ARIZONA

ACTIVE.—Prescott *Journal-Miner*, July 12: At no time in the past ten years has there been so much activity and legimate work in the mining districts which surround Prescott as can be noticed this year. If the number of mills now running, and the vast amount of money being expended in developing new and old claims, goes for anything, it shows, to say the least, an increased confidence in the worth of our mines, and that a new era has dawned upon this section. In nearly every district to the south of us will be found from four to a dozen claims in each of which as many miners are at work sacking ore for shipment, or else placing their properties in shape to yield. Stephen L. Mott is here, and with him came Johnson's pack train with 12,000 pounds of ore for the sampler. This last shipment will yield Mr. Mott at least $500 per ton, according to the judgment of experts. The main shaft on the Prince is down to a depth of 180 feet, with some drifting and stoping being done. Mr. Mott has purchased the Tuscumbia mill, and expects to have it in operation by the first of August on ore from several mines in the Peck district in which he is interested. Frank Kuhne has a force of men on the Belle mine, in Walker district, taking out good shipping ore. At present he has sacked, on the dump, ready for shipment to the sampler here, 60 tons, the first lot of 5000 pounds being brought in a few days ago by Joe Roberts. Seven tons of ore from the Amulet mine were received at the sampler on last Tuesday. This property is at present being worked under a lease, and is holding up remarkably well in the size and richness of the vein. The Dixie mill, on Lynx creek, is at present idle from lack of water, but a force of miners are at work in the company's mines extracting ore. A sale is reported of the Bullwhacker mine, four miles east of town, from J. R. Slack to Bashford & Burmister, for $3000. The Del Pasco mill is running night and day on ore from the Old Reliable. It is free gold and yields $25 per ton. Hon. W. A. Rowe is pushing work on his W. A. R. mine, near the Peck. He has one of the largest veins on the mountain and a good mine, from which he expects soon to ship ore. Shekels & Place are running their mill regularly on Crowned King ore, which is concentrated and shipped East. Pack trains are among the necessities miners are calling for at present. Those now in use have work for months ahead. O'Neill and Martin, of the Maggie mine on Turkey creek, have a carload of ore sacked and ready for shipment to Socorro, N. M. The Kansas City Co. have a force of 12

men working the Silver King mine, on Groom creek, outside of the disputed line of "agricultural" land. We hear they have struck good ground, the ore in character and richness being similar to that of the original vein. The Buena Vista mine, in Crook canyon, on which a couple of unique-looking arastras have been grinding out gold for the past two years, has been sold for $20,000. W. T. Hall is running through a lot of 30 tons of tailings from the Oxford mine on Groom creek, which yields $20 to the ton. A party of eight miners are prospecting in the Groom creek side of the Lynx creek mountains, and also doing some work on the old Parker mine in the same locality, which shows up well as work progresses. Frank Butler came in Tuesday with 7000 pounds of concentrates from the Crowned King mine, in Bradshaw district. The Lynx Creek Hydraulic Co. are at present surveying and looking over the ground on which the dam is to be built.

EUREKA DISTRICT.—Prescott *Courier*, July 3: John Lawler has gone to Eureka district, where about 50 men are at work in the Hillside silver mines, Eureka copper and others. Teams are constantly arriving from the Congress, with sulphurets. "Steve" Mott, the coming bonanza miner of Peck district, is working the Prince mine, pumping water out of the Black Warrior and getting the Tuscumbia mill in good running order. Twenty or 30 such men as Steve would make work for 1000 others and give us a much larger bullion product. There are men who honestly believe that the Crowned King mine, of Bradshaw district, is the best gold mine in the country. Mr. John White states that Yarnell & Co.'s big mine, near People's Valley, is the pride of that section of the country.

UNITED VERDE MINES, which were at one time considered of little value, are at present worth more money than some of our Arizona counties. They are worked by a miner, Hon. W. A. Clark, of Butte, Montana, and he knows a mine and how to work it.

HASSAYAMPA. — Mr. O. W. Stuht, just from Hassayampa district, tells us that himself and partners recently found an old mine which they have named the Aztec; that the ore mills between $20 and $25, gold; concentrates carry $10 more in gold, $30 in silver and about 5 per cent lead to the ton. They have cleared out part of the old cut, in which they found stone hammers and other tools; also charcoal. The cut, they think, is quite long. They work the ore in a 2-stamp mill. As this ancient mine is but about 12 miles south of Prescott, several people talk of going to it and seeing with 19th century eyes how pre-historic miners dug the precious ore. Geo. B. Ridenour is blasting 300-ounce silver ore out of his Delta mine.

BRITISH COLUMBIA.

TOAD MOUNTAIN.—Nelson *Miner*, July 11: The claims on 49 creek, about 8 miles southwest of Nelson, are looking good and improving as work progresses. Many of them are, as yet, mere prospects, but their owners have faith in the country, and know that there is always a ready market for free-milling gold properties such as they believe they have. Assessment and development work has been begun on many of the claims between the Silver King and the Toughnut, a distance of over 3 miles. At the Poorman, the 10-stamp mill is running during the day with satisfactory results, and ore hauling has been resumed. Twelve to 14 men are at work in the mine. Several claims on Anderson and Sucker creeks have been bonded or sold to parties who are handling outside money. The nickel claims on the north side of the river are attracting considerable attention, and are believed to be rich in ore, carrying that ductile metal.

COLORADO.

SALE.—Georgetown *Courier*, July 10: The Alexander lode, situated on Keith mountain, one mile up Mill creek from Dumont, was sold last week for the handsome sum of $80,000 to eastern parties, who have organized into a company known as the Alexander M. & M. Co. This sale is only a forerunner of a number of others which are to follow soon.

ORE.—During the month of June there was shipped from the Georgetown depot 61 cars containing 879 tons of ore, valued at $90,000; 23 cars went to Argo and 38 cars to Denver.

STRIKE.—A good strike has been made in the Luella mine over at William Forks. The vein of ore ranges in thickness from 12 inches to two feet, while it is not all solid, yet it is all pay. It mills 375 ounces silver and from 2 to 3 ounces gold to the ton. This ore body is continuous for 100 feet as far as yet known.

PIONEER.—Drifting and stoping is progressing on the lower level of the Pioneer, in which workings there is exposed about two feet of material, seven inches of which mills 6 6-10 ounces gold and $12 in silver to the ton. The remainder returns, under stamps, from 3 to 4 ounces gold to the cord.

THE MONTE CRISTO.—Aspen *Times*, July 12: Since the recent strike was made in the Monte Cristo, the company has been pushing work on the property most vigorously. The developments have been entirely satisfactory, but the ore has not yet come in in large quantities. The grade of the mineral that is found is very good and the shipments that are being made are more than enough to pay expenses.

THE EDISON.—The lessees of the Edison are driving work on the property and continue to find large bodies of very good ore. The regular rate of production that has characterized the mine for two months past is maintained and the grade of the mineral keeps up to 60 or 70 ounces.

LOWER CALIFORNIA.

FROM ALAMO.—*Lower Californian*, July 10: The El Paso Co.'s mill run through a lot of ore from the Scorpion mine, owned by McGrath and Joseph, last week which yielded 55 ounces of gold. The Princesa Co. melted $6000 into two bricks, which was the result of a long, uninterrupted run on ore from the San David, Princesa and Telémaco. These three are the company's producers at present. Hoisting works are in operation on the Telémaco, and Engineer Wright says they work to perfection. Mr. Poole is at present the foreman of the Telémaco. Wm. Lawry is foreman of the Princesa. Everybody is awaiting the arrival of the Princesa Co.'s big 10,000-pound boiler and heavy pumps. The Indian mine will then be put in operation, among others. The Santa Clara Co. is working steadily on the Encantada. Laoe's mill is kept busy as usual on custom ore. Kerr's mill is running again, making the fifth mill in actual operation.

CUCAPA.—F. B. de la Paht expects to hear almost any day of new and important discoveries in the Cucapa mining district, of which he is part owner. It is an immensely rich district in a variety of minerals, and with the 25 men now prospecting there, it will be strange if Mr. Piña's expectations are not realized.

GOLD.—Three new ledges of gold quartz were discovered during the past week by C. Castillo and Adolfo Bareño, about 100 yards inside of the old works of the El Pueblo mine, two miles northeast of the Real del Castillo.

MONTANA.

HELENA MINES LOOKING UP.—Montana *Mining Review*, July 12.—A few weeks since we mentioned the developments at Three-Mile, on the Branch to Marysville. On Monday last the first ore-car made its appearance on the spur at that camp, and after being filled with ore, reached Helena on its way to Omaha, last evening. This 20 tons came out of a 50-foot shaft and a 60-foot tunnel, without stoping or drifting. The president of the company, Mr. Wm. H. Morrell, who has been in Helena some weeks looking after his mines in person, returns East soon to procure machinery, etc., for the thorough development of the Three-Mile Group. Some of the ore assays high.

CASTLE DISTRICT.—Up to the present time only a small force has been at work on the Hidden Treasure, Castle district, simply prospecting the old works. Having satisfied themselves on this matter, a site for a working shaft has been located, and as soon as timber can be had a large force of men will be put to work. It is the design of the management to push the prospecting, both on the surface and underground, and sink the main shaft at the same time and employ at least 14 men steadily.

THE GRANITE'S OUTPUT. — Helena *Mining Journal*, July 12: The output of the Granite Mountain for the week ending July 3d was 52 bars of bullion, containing 76,576 ounces fine silver and 179 ounces fine gold. The silver product of the mine averages about 70,000 ounces per week. Roughly estimated, the value of this output at the prevalent price, $1.04, is $76,960, while at 92 cents, the late ruling price, the total of the same output would not exceed $71,080.

DRUM LUMMON.—*New Northwest*, July 12: The output of the Drum Lummon mine for the month of June was: Number of tons of ore crushed, 7067; total yield, $94,400; working expenses, $56,300. The Deer Lodge Mining & Reduction Co., a few days ago, shipped a half carload of ore taken from the levels and running 50 ozs. silver and 54 per cent lead.

NEW MEXICO.

HANOVER.—Silver City *Enterprise*, July 12: One of the most perfect successes attendant upon the inception, completion and operation of a mill or smelting establishment it has ever been the pleasure of the *Enterprise* to chronicle, is that of the Neff smelter on the Anson S. mine near the head of Hanover Gulch. The enterprise was a private one. The furnace is 30 tons capacity, and rated as one of Frazer & Chalmers' best water jackets. The copper product in ingots, is the finest that has ever been made in the country, and selected bars may be rated in commercial parlance as "wire copper" on account of its purity.

LONE MOUNTAIN.—The estimated output of the Good Luck mine since its location a little more than six weeks since, is over $8000. Eight hundred sacks are now ready for shipment. The Louise, the property of E. M. Young, at a depth of 13 feet is showing well. Elsewhere throughout the district there is considerable work going on and the annual product for this year, 1890, will exceed that of 1889 by $50,000, making in round numbers an output of $75,000.

PINOS ALTOS.—A contract of 150 feet has been let, for the sinking of a double compartment shaft on the Mammoth, one of the oldest locations in camp. This will open up immense bodies of ore, and furnish in connection with other properties an ample supply for the mill soon to be erected.

OREGON.

RICH STRIKE.—Baker City *Democrat*, July 7: The *Democrat* learns from what is deemed reliable authority that a rich strike has been made in the Monumental mine at Granite, operated and owned by the Eastern Oregon Gold and Silver Mining Co., Limited, of London, England. Our informant, who is a mining man, says that the vein is fully 18 inches wide and the ore will run from 500 to 1000 ounces to the ton. This is certainly welcome news, as no company operating in this section deserves success more than the company above named.

A BRIGHT OUTLOOK.—Mr. Geo. Robinson of Detroit, president of the Detroit Mining Co., operating the Lower Powder placers, spent several days in the city last week. The gentleman expressed himself as being highly pleased with the mining outlook of Baker county.

UTAH.

AT OPHIR.—Salt Lake *Mining Review*, July 9: The old Sparrow Hawk and Carrie Steele mines, six miles south of Ophir, are reported to be in the hands of new men, who have started to working them. These properties, years ago, had a stamp mill in operation and produced considerable bullion, but have been idle for a long time. New men and capital promise to make producers of them again at an early date. This locality is known as Lewiston in mining circles.

CRESCENT.—Salt Lake *Stock Exchange Journal*, July 11: Work on the Crescent, at Park City, is progressing famously. Mr. J. McGregor informs us that the concentrator is working to better advantage than ever before, and that the season's run would be a very prosperous one. The mine now employs 80 men. The product of the Crescent last month was $20,000. This mine has paid $228,000 in dividends and never made an assessment.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING JULY 8, 1890.

431,550.—BROILER—Wm. Brooks, Oakland, Cal.

431,872.—HEADLIGHT FOR LOCOMOTIVES—W. J. Burke, Seattle, Wash.

431,554.—CAR TRUCK—C. C. Butterbaugh, Los Angeles, Cal.

431,717.—HORSE FOOT PAD—F. M. Dreibelbis, Los Angeles, Cal.

431,662.—COMBINATION TOOL—F. Kortick, S. F.

431 607.—PULP DISTRIBUTOR—F. E. Monteverde, S. F.

431,708.—DAMPER—S. S. Richardson, Happy Camp, Cal.

431,676.—OPERATING ELEVATOR HATCHWAY GATES—C. P. Stanford, S. F.

431,788.—AXLE NUT—J. M. Thorp, Santa Rosa, Cal.

432,001.—HORSE COLLAR—T. J. Thorp, Flagstaff, Ariz. Ter.

432 002 —RUNNING GEAR FOR WAGON—T. J. Thorp, Flagstaff, Ariz. Ter.

431 680.—CABLE SHEAVE—F. B. West, S. F.

431,790.—AIR BRAKE—G. B. Williams, Portland, Oregon.

The following brief list by telegraph for July 15, will appear more complete on receipt of mail advices:

California—Henry Casebolt, San Francisco, excavating apparatus; George E. Crocker, Oakland, window-case hinge; William Davis, Los Angeles, cultivator; Willis S. Olletrap Pixley, washing machine; Robert C. Grimes, Santa Monica, attachment for lawn mower; Hiram B. Hanmore, Santa Cruz, covering for pipes; Alden D Kilhorn, Oakland, safety relief valve; John B Masters, Stockton, cotton harvester; Bartlett McIntyre, San Francisco, loading mechanism for wire rope transmission; Walter McQuille, Los Angeles, grass catching attachment for lawn mowers; Nathan W. Moody, Fresno city, fuse cap fastener; Orrin W. Parker, Oakland, wind-mill; Siggey D Smollianoff, San Francisco, assignor to the Americanite Manufacturing Company of Virginia, explosive compound; George A. Stom, Golden Gate, vehicle running gear; James Van Curen, Ferndale, sand-band.

Oregon—Alice M. Miller, Ashland, fruit boiler.

Washington—Joseph M. Clark, Colfax, double-acting pump.

Arizona—Louise J. Depuy, Phœnix, device for supplying gases and liquids to moving vehicles.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

DAMPER.—Samuel S. Richardson, Happy Camp, Del Norte county. No. 431,708. Dated July 8, 1890. This is a damper for stove-pipes and similar flues and smoke-conduits. The object is to provide a simple and readily operated damper, which can be readily inscrted in place without materially weakening the stove-pipe, and which, when in position, can be expanded or contracted, so as to adjust it suitably to the interior area of the pipe.

COMBINATION TOOL.—Frank Kortick, S F. No. 431,662. Dated July 8, 1890. This is one of that class of tools or implements which are designed for a variety of purposes, and are commonly known as combination tools. The implement is mainly used as a nail puller for boxes, but can be used as a wire cutter, as a mark scraper and as a prier for the bands or boops of boxes.

DEVICE FOR OPERATING ELEVATOR HATCHWAY GATES.—Charles P. Stanford, S. F. No. 431,676. Dated July 8, 1890. This patent covers certain details of construction by which the rising elevator opens the gates or doors which close as the elevator cage passes and on the return or downward trip the doors also open automatically for the elevator to pass and again close when it has gone by. By the peculiar construction the movement of the hatches or gates is made positive, the opening and closing being controlled by the movement of the cage.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

PACIFIC NOVELTY CO., July 12. Capital Stock, $25 000. Directors — George T. Ulmer, W. H. Brown, Albert Howell and A. D. Lockwood.

CALIFORNIA PRESSED BRICK CO. July 16. Capital stock, $150,000, Directors—W. A. Vandercook, J. K. Luttrell, J. A. Waymire, F. F. Ryer and J. E. Carey.

LOW ADJUSTABLE CAR CO., July 16. Object, to manufacture a patent street car, which can be used either as an open or closed car. Capital stock, $1,000,000. Directors—A C. Hamilton, J. B. Low, A. K. Grim, John H. Boalt.

PYRAMID HARBOR PACKING CO., July 16. Object, to pack salmon and other fish. Capital stock, $100,000. Directors—J. E. Gordon, E. B. Beck, Irvin Ayres and E. P. Stone.

MECHANICS' INSITUTE FAIR.—Mr. Culver, the superintendent of the coming fair, reports favorable progress and applications for 42,500 feet of space. Bids for the various privileges have been received. The United Edison Manufacturing Co. has made an offer to light the building and provide numerous electrical novelties for certain stated prices. It is desired this year to make the art gallery exhibit superior to previous ones. The prospects are bright for one of the most successful exhibitions ever held here.

The Mining Companies' Financial Standing.

The following is the financial standing on the first Monday of the present month of the mining companies listed on the two exchanges in this city:

*More assessments to come in.

†Bullion not sold, $129,599, with other shipments to be heard from. Mine expenses for June to come out.

‡June bullion output and mine expenses not included.

Mining Share Market.

The mining share market has been decidedly mixed under spasmodic business. Con. Virginia and Ophir fluctuated downward, while the other Comstocks, outside of Potosi, Bullion and Gould & Curry, showed slight fluctuations with no material change in prices. Potosi made some lively moves without any marked gain in price. Bullion and Gould & Curry scored an advance. The market to an outsider looks very much as if the ring has stocks to sell but fear that the public will sell and not buy if a decided advance is made in prices. It looks as if the new silver law is being worked to help in unloading, as is the "pumping racket" at the south end. If these fail to draw in large buyers at higher prices, then, of course, something else must be resorted to, probably a new (?) development. They have heretofore played the development "racket" quite successfully, and will if need be do so again so as to sell out at higher prices, after which more assessments and the public sellers at a heavy loss. In outside stocks trading was only fair. Bodie floundered about like a fish out of water. In the Tuscaroras and Quijotoas there was very little trading.

In another part (editorial) of the paper is given the latest advices received from Comstock mines. At a special meeting of the Bullion Mining Co., the management was turned over to Hayward and Jones. At the Savage Co.'s election the old board was re-elected.

The control of Best & Belcher and that of Gould & Curry appears to have passed into other hands. It is to be hoped that if any milling ore should be found under the new management, that the mine and battery assays will be given, as well as other needed reforms be brought about. Until the ring is retired and the mines honestly worked, outside dealers will have no chance to make money, but instead they have a certainty of losing their all.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none out worthy men.

J. C. HOAG—San Francisco.
R. G. BAILEY—San Francisco.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, $3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

MECHANICAL PROGRESS

A Novel Wrought-Iron Chimney.

The following, from *Industries*, are the particulars in regard to the mode of constnotion of a wrought-iron factory chimney of a somewhat novel description, which has been hnilt at Creusot. The total hight is 279 feet, the diameter 23 feet at the hase and 7 feet 6 inches at the top, the total weight being 80 tons, exclusive of masonry foundations. The latter are carried 3 feet 3 inches above the ground and weigh about 300 tons. The shaft was hnilt in successive rings, each 4 feet 1 inch high, the thickness varying from nine-sixteenths of an inch at the hase to one-fourth of an inch at the top. The nine lower rings were formed of 8 plates each, the upper ones of 4 plates each. The hase was encircled by a massive angle iron holted to the foundation. The 8 lower rings were lined with fire-brick. The erection of the chimney occupied 70 days, including taking down the flying scaffold. The latter was of a somewhat novel character. It consisted of a central wrought-iron tuhe 7 inches in dismeter, and provided at the hottom with 4 wooden crosshars or arms, so clamped that their length could he adjusted to suit the varying diameter of the chimney and carrying the internal platform. These arms rested on angle hrackets refitted to the interior of the plates The upper part of the central tuhe carried 4 cross-arms or jihs, each consisting of a pair of timhers stiffened hy raking strnts from the central tuhe. From their outer ends was slnng the exterior oircular platform.

The latter consisted of a pair of angle iron rings, to the outer part of which was riveted a plate iron fence, while the inner was provided with T-iron stanohions. Radial hearing timhers, resting on these rings, and adjnstahle endwise to snit the varying diameter of the chimney, carried the platform, an annular spsoe heing left just sufficient for hoisting the plates. The latter operation was effected hy a rope passing over an adjustahle pulley fixed to each jih in turn, and carried down a central tnhe to a snatch hlook fixed at the hottom of the chimney. As each succesaive ring was riveted np, two pairs of hars were laid across, hy whioh the scaffold was slung hy four jack-sorews furnished with ratchet oollars, and thus raised high enongh to take a hearing on the next set of angle hrackets. The oomplete scaffold weighed about 4 tons, and the heaviest plate about 8 hnndred weight. The total cost of the ohimney without foundations was about $8000.

A Chimney 460 Feet High.

Another chimney of most remarkahle character has been designed for the Royal Smelting Works of Saxony, Germany, hy Herr Heneicke, that is to he 460 feet high, with an inside diameter of 23 feet at the hase and 15 feet 6 inches at the outlet. The works will he connected with the chimney hy a horizontal flue 1093 yards in length, which crosses the River Mulda and takes an upward course of 197 feet to the top of the hill, where the giant ohimney will stand as an example of engineering skill. It will take 1,500,000 hricks to huild this perpendicular fnnnel, and its oost is estimated at ahout $30,000.

The Latest Theory on Boiler Explosions.

In a paper read hefore the Scientifi> Society of Bridgeport, Conn., Frank G. Fowler advanced the following theory on hoiler explosions: Many explosions take place when an engine is started—that is, when the throttle valve is opened and steam is drawn rapidly from the hoiler which had heen np to that time entirely olosed. Here the conditions approach thoae of the experiments—that is the hoiler still contains the air and other gases which it held when the fire was started, while the opening of the throttle produces a disturhance whioh, while less violent than a reversal of the hoiler would he, is sufficient to commingle the gases as above stated.

The class of hoilers in whioh explosions occur more frequently than in any other is the "rotary digester" nsed in many mills. In these hoilers there can he no suspicion of overheated crown sheets, low water or similar causes, as they are heated hy steam and not hy the direct application of fire. There is a continued introduction of water containing air and gases, and the hoiler itself is in constant rotation, so that those gases are thrown out and liherated from the water.

In fact hoilers seldom explode from "nnexplained" or "mysterions" causes when the engine which they supply is working steadily. Under these conditions the water in them is at least partially de aerated hy the drawing out of the steam; for while some air and other gases are introduced with the feed-water, the quantity in the hoiler is very mnch less than when steam is first raised hy starting a fire under a hoiler which is partly filled with air. Moreover, explosions in marine hoilers, whioh are fed with water from the condenser, or distilled water, are almost nnknown.

Experiments made hy heating closed hoilers until they explodéd showed that the destructive effects of the explosion are considerably greater where the hoiler is filled, say two-thirds, with ordinary hydrant water and the rest with air, than where the water has been de-aerated hy allowing steam to escape, carrying with it the confined air and gases, hefore the hoiler was closed and heated to the exploding point.

The anthor olaims that he has not hased his theory npon a single experiment, hut npon a series of experimenta repeated many times nnder conditions varying as much as possihle, and continned so long as to prevent any possihility of mistake; and npon these experiments he hases his explanation of those explosions which are called "mysterious."

PROGRESS OF STEEL POSSIBILITIES OF ALUMINUM.—An interesting feature of the recently published statistical report of the American Iron and Steel Association is the increasing percentage of steel in the total production. Ahout one-third of the har "iron" now manufactured in the United States is steel, so is nearly half of the plate and sheet iron, and 40 per cent of the cut nails and spikes. The rolled iron product, other than nails, only increased 7½ per cent last year, while the rolled steel product, apart from raile, increased 32 per cent. It needs not to say that steel ralls are now replacing those of iron on all the railroads which are efficiently managed. After that change is completed, what then? Will the next reform in order he wholesale snhstitution of aluminnm for the ferrio materiaal, crowding that out of the way as the latter is displacing wood for many structural pnrposes? It is not improhahle. Clay is much more plentiful than iron ore, and recent experiments at least indicate it as possihle that the new metal will ere long he produced as cheaply per unit of volume if not of weight, as its elder hrother. Such a change would revolutionize not a few of our manufactnring processes, and perhaps some of the hahits of the civilized human heing.—*Metal and Eisen Zeitung.*

STRAIGHTENING CASTINGS. — Sometimes a casting is warped in cooling and requires straightening hefore heing nsed. If the piece is to he planed or otherwise finished, it should he straightened hy heating and plaoing weights npon it. If it yields to this treatment it will retain its corrected form after the scale is removed, and throngh all the after processes. But, if the piece is to he used without finishing, it may he straightened hy "pening" with the hammer—striking with the "pene" or wedge-shaped end of the machinist's hammer. This process makes a series of indentations on the convex side of the iron, stretching the "skin" of the casting; hut when these indentations are removed hy after-working, the casting is liable to return to its curved form. In "pening," that portion of the casting that receives the hlow should he immediately over the face of the anvil or hench hlock; in other words, each hlow should find a solid resistance, and the casting should he moved along the face of the anvil as the work progresses.

ROPE TRANSMISSION OF POWER.—The utility of wire-rope transmission has hecome widely recognized; not only among the rugged hills and mountains of the East and far West, where streams go rushing down through caverns and rocky steeps, where no locations for mills or factories are afforded, is this means of transmission of precious power appreciated, hut it is so convenient to nse it that we find on the prairies of the West mills heing operated at a long distance from water-powers hy the wire rope. A few days ago, on a trip through Nehraska, we noticed a rope stretching for nearly a mile from a water-power to a mill that had recently heen hnilt adjoining a railroad, the owners finding it much more to their advantage to have it there, with the switching privileges afforded, than at the dam. The expense of hanling the flour which is thus saved to them will very soon pay for the system of power transmission.—*Modern Miller.*

THE MANNERMAN PROCESS, to which reference has already heen made in these columns, produces steel tnhes from the diameter of a pencil to 15 inches without the necessity of horing. A compound motion of rollers gives a spiral twist to the material in the process of rolling, thereby giving it a strength five to six times that of an ordinary tube of the same weight. The extreme compression to which the material is snhjected gives a quality which enahles the tnhes to he hent and twisted into any form without a flaw in the metal. One tuhe was snhjected to a pressure of 1700 atmospheres without yielding.

THE MANAGEMENT OF MACHINERY.—Prof. C. E. Tompkins, in a recent address said that it is not always the greatest amount of work that can he got out of a machine in a given time regardless of all other conditions that constitutes its economical use. The true economy in the use of all classes of machinery consists in obtaining the greatest amount of good work in a given time without material injury to the machine aside from its natural wear and tear.

HERE AND THERE.—Frank J. Sprague, an American writer, says the modern electric railway may he said to have heen horn in Europe; hut in its youth and younger manhood it is purely American. The compliment is returned hy London *Industries* which says: "It is to Americans that we owe almost all the recent developments in the steam engine. Novel hoilers, valve gears and framings are all of American origin."

SCIENTIFIC PROGRESS.

Rumination in Man.

"By rumination, or 'chewing the cud,' we designate a condition in which the food returns, without nausea, in small portions, from the stomach, through the œsophagus, into the mouth, some time after meals; here it is chewed anew and swallowed.

"Rumination helongs to the normal physiological processes of most herhivora, and forms the most marked characteristic of the whole class of mammals which we call 'ruminants.'

"Here the rumination is a most appropriate arrangement. The herhivorous animals are ohliged to partake of great quantities of food, as the nonrishing value of the grasses is relatively a small one. On the pasture they must make use of their time for gathering and swallowing the grass. Afterward, when they have more time and leisure, they redoce the food to smaller particles and mingle the same with saliva, hy the act of rumination.

"In view of this circumstance, the stomach of ruminating animals differs in construction from that of other animal classes. It consists of four compartments: Paunch, or rumen, honeycomh hag, or honnet, manyplies, or psalter, and reed, or rennet. The first two serve more or less as reservoirs, whereas the two latter contain the glandular elements for digestion.

"At the first act of swallowing, the food materials enter the rumen and the honnet, whereas, after chewing the cud, the food passes directly into the psalter and rennet.

"Chewing of the oud, which is so very important and appropriate for the whole olass of ruminants, occurs, though quite rarely, in man, and is designated then as rumination or merycism.

"For man rumination is unnecessary, and more or less a hindrance. One can hardly define rumination as a disease, for the hodily functions are in no way harmed hy that process, hut as an ahnormal anomalous condition, which must he socially an unoomfortable and disagreeable hurden to its owner."

The above is extracted from a paper recently read hefore the German Medical Society of New York hy Max Einhorn, M. D. The learned doctor described a number of cases of rumination in man, which had come under his knowledge, and he quotes from a large number of authorities on the snhject, dating hack to the year 1618.

Rumination, as treated in Dr. Einhorn's lecture, is very interesting, and appears in full in the *Medical Register* of May 17th.

ANTISEPTIC VALUE OF EUCALYPTUS —A late correspondent of the Selma *Irrigator* says: In soaking up old wine or vinegar casks, we throw a few hlue-gum honghs with their leaves into the water, and it never hecomes putrid, while without the hlue gum we would have to change the water daily to prevent putridity and spoiling of the flavor of anything afterward kept in the cask. We have kept fresh heer e ght days in the hottest weather, hy keeping around it a plentiful supply of green hlue-gum leaves, and changing them daily. A decoction of green leaves is a stronger and more lasting stimulant than tea or coffee, and more salntary in its effects, as it does not cause wakefulness. It seems to have the stimnlating effect of quinine, without any of its injurious qualities. In addition to the above it may he remarked that no worm or insect is ever fonnd upon the eucalyptus tree, or in the earth where its roots permeate. A row of trees planted through an orchard or vineyard will cause insects, worms and caterpillars to vacate that region. The hranches of the eucalyptus nsed in the rooms or windows, or as decorations in dwelling rooms, will cause mosquitoes, moths, fleas and flies to leave the premises, and when the leaves are placed heneath a carpet aronnd the horder of the room, when the carpet is laid, is an insurance against the moth, and hranches placed heneath the hed pillows a protection against fleas.

ELECTRICITY IN AGRICULTURE —The application of electricity to agricnltnre has recently received some attention in France. In an article upon this snhject in *La Lumiere Electrique*, it is pointed ont that seeds which are snhjected to the action of the current hy placing them when wet hetween copper electrodes in long glass cylinders open at hoth ends, and sending a current throngh them from one to two minutes, develop more rapidly and more completely. The plants which resulted from the electrified seeds were larger and of hrighter color than plants from other seeds, hnt the current had no effect on the yield. In the case of peas, heans, harley and sunflower seeds, development took place in from 40 to 60 per cent less time than when the seeds were not snhjected to the influence of the current hefore planting. When large plates were sunk in the earth at opposite ends of the garden plot, and a current passed hetween them, the result was a larger orop, and the growth of vegetahles of enormous size.

THE MOON'S HEAT.—The problem of measuring the moon's heat, says the *St. James Gazette*, has heen solved at last hy Mr. C. V. Boys, one of the professors at South Kensington. By means of quartz filaments he has produced a thermopile of almost fluoredihle delicacy. By this remarkable apparatus he can render sensihle the heat of a candle up to the distance of a mile and three quarters, and hy directing the minute disk of the instrument to the moon he has shown that the warmth received from its reflected light is equal to that given out hy a candle at 21 feet distant. Observation seems to show that, although the moon's face is under the hlaze of an unclouded sun for fourteen days, it remains comparatively cool, and that whatever heating it does ultimately receive is rapidly gained and as rapidly lost.

THE VARIOUS CONDITIONS OF STEAM —We notice, says the Boston *Journal of Commerce*, that many engineers have not quite clearly fixed in their minds the meaning of the terms saturated and superheated steam, particularly the former. Steam may he dry, contain no water, and yet he saturated. Steam not heated above the temperature due to its pressure is said to he saturated, even though it contains no water. If the application of any pressure or the abstraction of any heat would cause steam to hecome a liquid, then that steam was saturated steam. Steam hoiled from a kettle has no moisture; it has a temperature of 212°; it is a dry steam, yet saturated steam; hut the application of pressure or taking away of heat would change it from a vapor to liquid. If the steam issuing from the kettle was heated to 220°, it would stand considerable pressure and the abstraction of heat without changing its form. This is superheated steam. The other, although dry, is saturated steam, this term not requiring the actual presence of moisture.

"BUMPING" OF BOILING LIQUID.—During the distillation of fluids, great inconvenience is frequently experienced, due to the unmanageable "humping" of the boiling liquids. This can be prevented hy placing in the fluid a spiral coil of platinum wire, the coil inclosing some small fragments of pumice stone. The specific weight of the apparatus must he great enough to sink it to the hottom of the receptacle. By this method the liquids hoil quietly. Ashestos of long fiher also answers the purpose perfectly, a hall of the fihers the size of a hazel-nut, placed in the retort, making it possihle to carry on the distillation with safety.

THE EIFFEL TOWER IN A THUNDERSTORM.—From recent experience during thunderstorms, the Eiffel tower at Paris seems to he proof against lightning. On one occasion it was snhjected to a remarkable hombardment from aerial electricity, heing struck hy lightning no less than six times in 11 minutes. Three of the flashes are said to have reached the top of the conductor simultaneously, resulting in a remarkable display and considerable vihration on the part of the hig iron frame. A rattling of the metal was heard, hut no apparent damage was done.

A NEW PROPULSIVE FORCE —It is said that Paul Clifford, a French scientist, has discovered a new propulsive force in a condensed liquefied gas. Three hundred drops of this compound was contained in a small steel receptacle under a rifle-harrel, and each time the trigger was pulled one drop falls into a hreech hehind the hullet. Contact with the air causes it to volatilize instantaneously with an expansive force far exceeding gunpowder and expels the hullet with terrihle velocity, unaccompanied hy either noise or smoke.

BLACK SULPHIDE OF SILVER is now hsing used hy a Parisian firm in the manufacture of all sorts of jewelry, and gives a very pleasing result. The hluish-hlack surface of the metal is stamped with gold and silver designs, apparently in the same way as tortoise-shell work, and the ontcome is a very pretty and tasteful ornament. For mourning jewelry and table ornaments this new process (in which, hy the way, the hlack silver is permanent) ought to prove very tasteful.

SOMETHING NEW.—A new use for the silversmith's art has lately heen developed in Providence, which will probably demand the attention of the world and hring fame to the discoverer of this new feature. This new idea is the oxidization in silver of natural fruit and flowers—something that heretofore has heen only known to the French silversmiths, the secret process heing guarded closely and jealously last it should hecome known ontside of France.

THE LIGHTNING'S FLASH.—Scientists say that the duration of a lightning flash is not infinitesimal, hnt that the flash lasts a measurable time. For example, if one sets a camera in rapid vihration and exposes in it a plate, so as to receive the impressions of the flash, it is fonnd that the impressions appear widened ont on the negative, showing the negative to have moved during the time the flash was in existence.

HIGHT OF LUMINOUS CLOUDS.—A number of photographio impressions of luminous clouds have heen taken during the current year in Germany. The result of comparing the various results obtained at different observatories goes to show that these clouds have the extraordinary altitude of 5½ miles above the sea level.

THE LARGEST STEAM DERRICK in the world is used hy a shipping company at Hamhurg, Germany. It is used for lifting immense weights on and off shipboard, and can pick up a ten-wheeled locomotive with ease.

GOOD HEALTH.

How to Live.

There are twn tbings we chiefly wish for while we llve—health, to make life enjoyable, and length of days to make it lasting. To obtain hcth mainly depends on onrselves.

We do not simply die; we usually kill onrselves. Onr habits, our passions, our anxieties of body and mind, shorten our lives.

The key to health and long life is sobriety in llving. It is tbe fashion to restrict the term sobriety in the nse of intoxicating liqnors.

We say with truth that the drunkard is killing himself, hnt we rarely speak of overeating as a shortener of life.

A sober life implies moderation in all things. "It consists," says Cornan, "in moderate eating, in moderate drinking and in a moderate enjoyment of all tbe pleasures of life; in keeping tbe mind moderately but constantly employed, in cnltivating the affections moderately, in avoiding extremes of heat and cold and in shnnning excessive excitement either of body or mind. A sober life is a life of order, of rule, of temperance—tbat divine sobriety which is grateful to God, friendly to nature, the daughter of reason, the sister of virtue, the companion of temperate living—modest, gentle, content with little, guided by rule and line in all its operations."

It is an important rule to observe and practice for health, comfort nnd onr pence within and without, to attack every ailment and malady at its beginning, to arrest the premonitory symptoms before they take root in our vitals, and gradually or quickly interrnpt the normal action of the organs. A loss of strength, a weakened memory, a tottering walk, all bespeak a mental or physical disorder, which, if not arrested in the early stage, will lead to disease and fatal consequences.

"One can hardly believe," says Reveille, "bow far a little health, well treated, will carry ns."

"And the rule of the sage," says Cicero, "is to make nse of what one has, and to act in everything according to one's strength."—*Ex.*

Leprosy of the Middle Ages.

According to Dr. Morell Mackenxie, leprosy, the sconrge of the middle ages, has not become practically extinct among Enropeans, hut is in reality spreading. It has between 1000 and 1200 victims in Norway, is also found in Portugal, Greece and Italy, and is rapidly spreading in Scily, in the Baltic provinces of Russia, and in France, while the British Islands are not exempt from it.

In the United States cases have been fonnd in California, in some of the States of the Nortbwest, in Utah and in Louisiana. Many cases exist in New Brunswick. In the Sandwich Islands the disease first broke ont in 1853, and there are now 1100 lepers in tbe Molokai settlement alone. The diseace is extending in the West Indies.

The Treatment of Leprosy.

Kate Marsden, whose investigation of leprosy in Rnssia has been mentioned frequently, had interviews with M. Pasteur with the view of ascertaioing whether inoculation could be resorted to. M. Pasteur, however, could hold ont no hope of leprcsy being dealt with in that way. Miss Marsden is anxious that this negative resnlt shonld he promptly known in New Zealand, where hopes have been entertained of the applicability of the Pasteur treatment to Maori lepers. Miss Marsden is about to return to Russia to continne her investigation.

AN AID TO CURING ALCOHOLISM.—We believe that the best authorities are generally skeptical as to there being any sure cure for confirmed habits of inebriety, nnless tbe effort in that direction he aided hy a strong exercise of the will of the nnfortnnate subject of this bad habit. There are, however, many remedies recommended as aids in diverting, or, in a minor degree, satisfying the appetite for strong liquors, which are nndonhtedly of great advantage in some cases; and one of these is thus recommended by a self-styled "rescued man:" "I was one of those unfortunates given to strong drink. When I left off, I felt a horrid want of something I must have or go distracted. I could neither eat, work, nor sleep. Explaining my affliction to a man of mnch edncation and experience, he advised me to make a decoction of grnnd quassia, a half-ounce steeped in a pint of vinegar, and to pnt abont a small teaspoonful of it in a very little water, and to drink it down every time the liquor thirst came on me violently. I found it satisfied the cravings, and it diffused a feeling of stimulus and strength. I continued this cure, and persevered till the thirst was conquered. For two years I have not tasted liquor, and I have no desire for it. Lately, to try my strength, I have handled and smelt whisky, but I have no temptation to take it. I give this in consideration of the nnfortunate, several of whom I know have recovered hy means which I no longer require."—*Scientific American.*

THE USES OF SAWDUST are daily becoming more varied. It has recently been utilized for the manufacture of paper pulp and sheathing paper. It has also been discovered that fine sawdust is unequaled for the dressing of wounds and as a vehicle for medicaments or antiseptics. The sawdust, when freed from splinters and sharp bits of wood and used alone and dry, is a clean and pleasant dressing; it readily takes up and holds the discharges without packing or adhering, and is readily rendered antiseptic hy any of the methods used in the preparation of antiseptic wool and cotton. It is suggested that the yellow pine sawdust, being rich in turpentine, would prove a valnable antiseptic application.

DANGER IN STALE MEAT.—A man was found dead some two years ago in a lodging-house in this city. An analysis of the contents of his stomach was made, and the following report handed in to the coroner: "I have made a chemical and microscopical examination of the stomach and contents of John Dwyer, which shows that his death was probably caused from eating mince pie containing tainted or partially decomposed meat. The chemical analysis demonstrated the presence of a poisonous cadaver alkaloid."

USEFUL INFORMATION.

VALUABLE POINTS BY A PLUMBER.—"If you want a point or two about cleaning waste pipes without sending for a plumber," said a retired member of the fraternity to a New York *Telegram* reporter, who was complaining of the trials of house-ownership, "just listen to me. If I were still in the business I would not give away what I am going to tell you now, hnt as I am out of it I do not see why I may not help a friend. One of the most frequent and trying annoyances," he continued, "is the obstruction to the free, quick outlet of the waste water of the wash-basin, the bath-tnb and kitchen sink. This is caused hy a gradual accumulation of small bits of refuse material, paper, rags, meat-bone or grease, which check and finally entirely stop the outflow of the waste, and then the plumber is called to remove the stoppage with his force-pomp. Sometimes this is accomplished, hnt often the pipe has to he cut, and there is great inconvenience and expense. Just before retiring at night, pour into the clogged pipe enough liqnid sodalye to fill the 'trap,' as it is called—or the bent part of the pipe jnst below the ontlet. Be sure that no water runs into it nntil the next morning. During the night the lye will convert all the offal into soft soap, and the first corrent of water in the morning will wash it away and leave the pipe as clean as new. See? This is practical chemistry, yet few chemists would ever think of it."

WHITE LEAD INJURIOUS.—It is said that painting floors with any color containing white lead is injurious, as it renders the wood soft and less capable of wear. Other paints without white lead, such as ochre, raw nmber or sienna, are not injurious and can be used with advantage. Varnish made hy drying lead salts is also said to he destructive, and it is recommended that the horate of manganese should be used to dispose the varnish to dry. A recipe for a good floor varnish is as follows: Take two pounds of pure white borate of manganese, finely powdered, and add it little hy little to a saucepan containing ten pounds of linseed oil, which is to be well stirred and raised to a temperatore of 360 degrees Fahrenheit. Heat 100 poonds of linseed oil in a boiler nntil ebullition takes place, then add to it the first liqoid, increase the heat and allow it to boil for 20 minutes. Then remove from the fire and filter the solution through cotton cloth. The varnish is then ready for nse, two coats of which may he used with a final coat of shellac, if a brilliant polish is required.

A PROBLEM DEFYING SOLUTION.—The Boston *Herald* has the following nut to crack: Assuming tbat a community of 100,000 workers can produce in a day hy the labor of 10 hours, wealth to the value of $300,000, then if their labor is cut down to eight hours a day, they must either work harder or more skillfully in the shorter period, or there will be one-fifth less wealth to divide among those interested in its production. There is no way of getting over this. At the present time the wages earned are paid, and the capitalist receives his returns from the gross sum of production. If this sum le cut down in any way a loss is inevitable either on the side of the capitalist or wage-earner, or on both sides. While $5 divided among five men will give each $1, there is no process of arithmetic hy which $4 divided among five men will produce the same result.

NOVEL USE FOR BAND SAWS.—The band saw is becoming more popular every day and new uses are found for it from time to time. The Egan Company of Cincinnati, Ohio, are often called upon to adapt it for purposes seldom thought of. A short time since the United States Surgical Bureau at Washington, D C., requested one arranged to saw human skulls and bones. It was a success. Recently this same firm devised a band saw to cut out men's pants from jeans and wool cloth; this it does without fraying at the edges in any way, making a clean and rapid cut; what next?

KEROSENE AND SPIDERS.—A correspondent of the *Scientific American* writes that journal as follows: Did any of your readers ever hear that kerosene attracted spiders? I have a large can of kerosene in a shed, and under the faucet to catch any drops in drawing the liquid, is a tin. Repeatedly I have found this kerosene tin filled with spiders, large and small, which have been drawn to it apparently, for they are not to he seen in the room elsewhere. I should have supposed the smell of kerosene would repel any insect, but these spiders come to the tin as if it were a trap for them, and of course find their death in it.

ELECTRICITY.

Electric Tanning.

The London correspondent of the *Electrical World* writes to that journal as follows in regard to a recent exhibition of the process of electrical tanning: A large party of experts and members of the technical press, lately visited the works of the British Electric Tanning Co., at Rotbsay street, Bermondsey, for the purpose of witnessing the process of tanning hy electricity, which has been in operation on a commercial scale since September last. After the preliminary processes of soaking the skins and denuding them of hair, the hides are placed in revolving drums containing the ordinary tanning liqnor, with the addition of some turpentine. Through these drums, which are 77 feet 6 inches in diameter, and which revolve at a speed of about eight revolutions per minute, a current of ten amperes at a pressure of 100 volts is passed. In the ordinary process of tanning, which takes from five to six months, the mixture of acids and gelatine gives rise to an almost impenetrable coating on the exterior of the hides, and it is the formation of this coating that makes the ordinary process of tanning such a lengthy business. What part is actually played hy the electricity *per se* is by no means quite clear, but it is supposed that the remarkable way in which the process is reduced, viz., to five or six days, is due to the ordinary diffusive action of the electric current, superadded to the heat caused by its passage and the pressure of the gases evolved in the hermitically sealed drums. A large quantity of hides tanned by this process was shown, and many tanning experts expressed themselves much astonished at the results. The British Electric Tanning Co. owns the patents of MM. Worms and Bale. A process of electric tanning, in which the hides are hung on a revolving frame, has been devised hy M. Groth, but I do not think this process has yet been brought into commercial use.

ONE OF THE LATEST APPLICATIONS of electricity that has been reported is to what is called a locomotive telephone. It was tested recently on the B. & O. railroad, and is said to have worked very satisfactorily. The apparatus is described as consisting of a single iron bar laid between the tracks, through which a current of electricity is passed. A brush is fixed upon the engine, which is at all times in contact with the bar, and when two engines approaching each other get within a mile or more apart, bells ring in the cabs, and after the engines have been stopped the engineers can make use of the telephone in abusing each other for being "on my time." This may be a very good thing, says an exchange, but if the uncertainties of the ordinary telephone are any criterion by which to judge, those bells will be very likely to ring at wrong times and give false alarms until they are paid no more attention to than was the boy who cried wolf when there was no wolf, or they may fail altogether. We pin our faith to the block signal.

STEAM BY ELECTRICITY.—A correspondent of the Baltimore *Manufacturers' Record* writing from Chattanooga, Tenn., says: A wonderful invention that will be of great importance to the manufacturing world is being perfected in this city. It is a process for raising steam by electricity. Experiments which have been made on a small scale have been entirely successful and a plant is now being put up to develop the uses of the invention to an almost unlimited extent. The idea is to generate the electricity at a coal mine, or perhaps at a number of them, within a few miles of this city, and bring the electricity to this point by the usual method of the wires. It requires but little figuring to comprehend the saving of money that can be accomplished hy this method of generating steam. Of conrse, it removes all expense of transportation and handling of coal, and is free from all dust and dirt. Its application to the boiler is accomplished hy simply turning a key, which can be done hy a child.

"THE DANGER of an ignorant person in seizing an electric wire carrying a strong current is as great as that to which a person ignorant of the ways of snakes would he subjected if he undertook to take the place of the skilled observer, accustomed to put his arm into a tall jar containing rattlesnakes and take them ont," is Prof. John Trowbridge's graphic illustration of one source of danger connected with electric wires.

ELECTRIC MOTORS IN USE.—It is stated by one of the best known manufacturers of motors in the United States that to-day there are no less than 15,000 motors in use, applied to not less than 200 different industries, and an industrial revolution is taking place equaling, if not surpassing in importance, that attending the introduction of the steam engine, and marvelous in the rapidity of its growth.

ENGINEERING NOTES.

Utilizing Tides for Power.

A Chicago engineer, named C. M. Bartlett, has invented a system of utilizing tidal energy, which is thus described:

A dam several feet above high-water mark is first built across a tidal inlet in such a way as to inclose a space of as large capacity as possible within the predetermined cost of construction. This space is then divided hy a partition dam or orib work into two receptacles as nearly as possible of equal capacity. A considerable economy of power can he effected hy further partitioning off a small area in that quarter of each receptacle which lies adjacent to the ocean and to the main partition dam. Essentially the effect will he to create two sets of receptacles having directly opposite functions. One set of these receptacles will he opened only at high tide, and thus kept as full as possible at all times. In it and adjacent to the main partition dam, that is in the small area which has been partitioned off in this set, will be placed a float of sufficient extent and buoyancy to sustain the necessary machinery and buildings. The power will be generated by means of a current of water drawn by a syphon from this reservoir through a reversed turbine water-wheel and into the other set of receptacles. These latter will he opened only at low tide, and thus kept as nearly empty as possible at all times. During high tide the water drawn through the syphon will of course accumulate in this waste water receptacle and to the extent of its rise therein tend to diminish the effective head of water, hnt it is during this very time that the water in the other set of receptacles is highest and when, with the ebb of the tide, that water is no longer added to, and is therefore diminishing hy reason of the drain through the syphon, then at this time the water in the waste water receptacles is also being drained through the ocean gates of those receptacles in the wake of the outgoing flood. Thus the difference in level between the water in the two sets of reservoirs is maintained at a comparatively unvarying figure. This head of water will, of course, depend upon the highst of the tide and the amount of power desired, but will never be less than two-thirds of the difference between high and low water.

It will thus he seen that the system invented hy Mr. Bartlett comprises:

1. A combination of reservoirs insuring a constant fall of water in one direction.

2. A combined float and syphon automatically adjusting to the rise and fall of the water, and making nse of every inch of head and dispensing with the nse of stationary gates and turbines.

3. The automatic balancing of the turbine, hy placing it in an inverted position in the upward stream of the syphon, thus opposing the force of the stream to the gravity of the wheel and shaft, and avoiding a large percentage of the friction and wear which constitutes the *bete noir* of hydraulic engineering in placing turbines where gravity and the force of the stream act in the same direction.

THE ALASKA RAILROAD.—The subject of bridging Behring Straits is coming up again in a lively manner. Charles L. Colby, with a party of engineers from New York, is said to have gone to Alaska to examine the ground; General Butterfield is reported to he representing the project at St. Petersburg, and Governor Gilpin is drawing attention to it hy conversations with all who take an interest in the subject. It is evident that the *pros* and *cons* are in a fair way of being ventilated. Behring Straits may perhaps become as familiar a topic of discussion as it was in the old days, before the Atlantic cable was laid, when a company was formed to connect Russia and the United States hy a telegraph line via Alaska and Siberia. In these days nothing seems impossible. Railroad-builders can be found who will take a contract to build a line between almost any two points on the globe.

THE GREAT NEW WATERWAY.—The survey of the proposed ship canal from Lake Erie to the Ohio river, has had important results. The project is pronounced hy the engineering corps entirely practicable. A line has been successfully run from the lake to Beaver county, which, when finished, will not exceed 103 miles in length. It crosses the summit 67 feet lower than the old canal did. There is found to he an ample water supply, and plans are made for storage reservoirs.—*Pittsburg Dispatch.*

WATER-WORKS.—It is said that water-works in the United States and Canada have about trebled in the last ten years, growing from 660 in 1881 to 1900 to day. The capital invested is $500,000,000, their annual revenue is $50,000,000, their mains are 30,000 miles long, and they have 2,000,000 taps.

OCEAN SPEED.—An ocean steamer has been projected which, it is claimed, will cross the Atlantic between Queenstown and Sandy Hook in about three days and 13 hours, averaging a speed of 21 to 24 knots an hour.

SETTLING.—The report that the Thames river bridge was settling is true, but there is nothing dangerous in the settling which has taken place, some four or five inches at one end of a 310-feet span.

TABLE OF CONTENTS.

EDITORIALS.—Passing Events; Silver; The Comstock Mines; Death of General Fremont, 40. Academy of Sciences; Settling-Boxes, 41.
ILLUSTRATIONS.—Gen. J. C. Fremont, 33. View of the Southern End of Lake Zurich, 35. Pointed Settling-Box for Quartz Mills, 41.
CORRESPONDENCE.—The Gold Belt of Northern California; San Bernardino County, 34.
MECHANICAL PROGRESS.—A Novel Wrought Iron Chimney; The Latest Theory on Boiler Explosions; Progress of Steel—Possibilities of Aluminum; Straightening Castings; Rope Transmission of Power; The Mannorman Process; The Management of Machinery; Here and There, 38
SCIENTIFIC PROGRESS.—Rumination in Man; Antiseptic Value of Eucalyptus; Electricity in Agriculture; The Moon's Heat; The Various Conditions of Steam; "Bumping" of Boiling Liquid; The Eiffel Tower in a Thunderstorm; A New Propulsive Force; Miscellaneous, 38.
GOOD HEALTH.—How to Live; Leprosy in the Middle Ages; An Aid to Curing Alcoholism; The Uses of Sawdust; Danger in Stale Meat, 39.
USEFUL INFORMATION.—Valuable Points by a Plumber; White Lead Injurious; A Problem Defying Solution; Novel Use for Band Saws; Kerosene and Spiders, 39.
ELECTRICITY.—Electric Tanning; Steam by Electricity; Electric Motors in Use; Miscellaneous, 39.
ENGINEERING NOTES.—Utilizing Tides for Power; The Alaska Railroad; The Great New Waterway; Water Works; Ocean Speed; Settling, 39.
MINING SUMMARY—From the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Wyoming, 36-37.
MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 44.
MARKET REPORTS.—Local Markets, Eastern Metal Markets, 44.

Passing Events.

While the silver bill signed this week by the President is not all the miners desired, it will doubtless serve to make a better business out of silver mining, and a revival of that interest is looked for. Many low-grade properties, which have been idle for many years, may now have an opportunity for some profit.

The molders' strike still continues with few changes. The men have gone out of one more foundry—Huntington's. Men are still being brought from the East by the foundrymen, and a small percentage of each lot is still being "captured" by the molders. Meantime the shops continue their work about as usual, though, of course, with some inconvenience.

The courts have decided that although a mine may be in a foreign country and its owners foreign, if a contract for purchase is made in California, and the mine is alleged to have been "salted" on the purchasers, the courts of this State have jurisdiction in a trial of the case.

Another Government vessel, built here by the Union Iron Works, is about ready for her trial trip. Meantime, other war-ships are in course of construction at our local ship-yards.

ABOUT $75,000 or $100,000 worth of California marble will be used in the new Mills' building, at the corner of Montgomery and Bush streets, in this city. It will be taken from the quarries in Inyo county.

Silver.

While the Silver bill, which has just become a law, does not place silver exactly where it should be, and still treats it only as a marketable commodity, it is a very long stride toward ultimate free coinage, which may come at the next session of Congress. The new law makes the purchase monthly of four and one-half million ounces of silver compulsory, if offered, and provides for the issuance of certificates, based upon silver, receivable for all private and public debts.

The law is one which will be specially beneficial on this coast, where, since the demonetization of silver, the miners of that metal have been crippled. The heavy discount which has prevailed for so long has made hundreds of mines unprofitable, and in all the silver mining regions numbers have had to close down, throwing thousands of men out of work and entailing great loss upon owners of such properties and the towns dependent on their operations.

In California we were never heavy producers of silver, a couple of million dollars being about the annual output. Still, such mines as those at Calico, and others in San Bernardino county, and still others in Inyo county, have had hard lines for years, many having closed down. In Nevada, there are dozens of mining districts which have been languishing in comparative or positive idleness which should have been, and now will be, active silver producers. The Comstock itself, even though its ores produce so largely of gold, has suffered to considerable extent. Utah, Colorado, Idaho and Montana have all felt the effects of silver depreciation badly, though the latter State is, notwithstanding, the most prosperous mining region in the United States.

With the Government guarantee of certain purchase, a market is assured for the product and much higher prices are expected than prevail at present, though they are now much higher than at this time last year. Doubtless, many mines that have been idle will be started up again and "lively times" come again once more in some of the old silver camps of the coast.

As has been pointed out, however, in these columns, it is not only the silver miners who will be benefited by the enactment of this law, but the farmers, manufacturers and labor interests as well. The details of the law were printed in the PRESS of last week. Silver will still, as a commodity, be subject more or less to speculative influences, but this must be submitted to for the present. The silver men are to be congratulated in having accomplished an advance step, and it only remains to exert such influence as shall, at the next session of Congress, again ennoble the white metal.

A broad effort is to be made to firmly fix silver money in the policies of the American nations. Last week Senator Teller introduced a joint resolution declaring it to be the determined policy of the United States to use both gold and silver as full legal tender money, and instructing the President to invite the Governments of the Latin Union countries and such other nations as he may deem advisable to join the United States in a conference to adopt a common ratio between gold and silver for the purpose of establishing the international use of bimetallic money and securing a fixity of the relative value between those metals, the conference to be held at such place as may mutually be agreed upon by the Executives of the Governments joining in it.

THE MOLDERS' STRIKE.—The shop of F. A. Huntington has been added to those affected by the molders' strike. Mr. Huntington borrowed from the Pacific Iron Works a pattern of an amalgamating pan for which he had an order and he was told by the President of the Union that if he made any articles from those patterns his men would be called out. He concluded to close his business rather than be dictated to, and paid his men off. There were eight molders in this foundry. Another non-Union molder from the Fulton Iron Works was assaulted by strikers while going home from work on Saturday night. Thirty molders came from the East this week, 13 of whom are at work in the foundries in the places of strikers.

THE coal miners at Gallup, N. M., are on strike for a raise of 15 cents per ton.

The Comstock Mines.

All information received from Virginia, Nev., is confirmatory of more active work being done in the Comstock mines than for several years. Prospecting drifts and crosscuts are being run in, with the work tending toward the west lode, which is nearly all gold-bearing. That the work going on is of an important character is evidenced by leading superintendents paying more personal attention to the work than they have for two years past.

From our own and other advices from the mines we give the following brief statements:

Drifting south has commenced on the 1030-foot level in Potosi. In Alpha, on the 600-foot level, they have started a southwest drift to tap the Confidence-Challenge ledge which extends through Con. Imperial. The Hale and Norcross managers are building another reservoir to catch the rich slum that is allowed to escape through their peculiar mode of milling. Our correspondent says that this slum assays from $30 to $40 a ton, which he thinks "is very good alum to come out of $20 ore." He writes that in Overman the ore in the winze widens and improves with depth. In other parts of the mine good ore is found. He asserts that the mill assays should run higher on present showing.

In Confidence, on the 1000 foot level, they are in good ore assaying $60 a ton, which they are running out through Yellow Jacket, but of which no further record is kept. He writes that Hale & Norcross takes out 28 carloads (seven tons to the car) of ore a day, which is put through a milling process peculiar to that section. In Best & Belcher the work is growing more interesting, as it is in Sierra Nevada and Mexican. Utah is doing some important work which deserves watching. Savage is reported to be looking well, but experienced miners fear that old timbers may be run into before long. It is reported, but how correctly we can not say, that the Hale & Norcross shaft will have to be repaired and otherwise improved. The active prospecting work going on in Con. Virginia ought to show good results soon. Mysterious hints about Yellow Jacket are still afloat. In Kentuck, they have commenced drifting on the 1000-foot level. Official letters received (Wednesday) from the Gold Hill mines report that in Belcher they are stoping out on the 1000 and 300-foot levels in 12 feet ore; 362 tons of ore milled assayed $19.66 per ton. The superintendent of Crown Point does not report anything new in the mine, but instead he sent to the office in this city $9,888, which is the net result of last month's work. This money covers the company's June indebtedness, and gives them a "carry-over" of about $550. In two levels in Sag. Belcher they are getting into ore.

The Late Chas. H. Chamberlain.

On Thursday night of last week, ex-Judge Charles H. Chamberlain died in Oakland, at the age of 70 years and eight months. He was a pioneer of this State, having arrived in San Francisco in August, 1849. He started immediately for the mines on the Mokelumne river, going afterward to Montezuma, Tuolumne county. In the spring of 1850, he worked in Soldiers' Gulch, near Tuttletown, and still later, at Dusty Bar and Grand Bar on the Stanislaus river, and at Little Garrote. In 1851, he was at Tuttletown, mining as before, and went in the fall of that year to Columbia. When the celebrated Coolie bill passed the lower house of the Legislature, in 1852, authorizing all persons, who desired, to make contracts in China and the South Sea islands with the people of those countries to labor in California for a period of ten years, and the enforcement of such contracts by imprisonment, Judge Chamberlain, with others, recognized the measure to be an attempt to introduce slavery into the new State. Runners were sent about to call the miners together to denounce the measure, and he drew up the resolutions which were adopted, which were the means of calling public attention to the evils of the bill so that it was eventually killed in the Senate. About the same time he wrote against Chinese immigration, originating many of the arguments since used on that subject. Among the many other public-spirited acts of this gentleman may be mentioned the fact that he drafted a system of mining laws for the miners of Tuolumne county which were remarkable for their equity and justice.

During his career in California, Judge Chamberlain has been a member of both the Senate and the Assembly, having been elected from San Joaquin county. In 1866, he was appointed Receiver of Public Money at San Francisco, which position he held for nearly 20 years, and most of those who had business at the Land Office will remember him. He was an intelligent and progressive citizen who had a host of friends throughout the State. He was a member of the Society of California Pioneers, the State of Maine Association, and the Tuolumne County Association. Judge Chamberlain was always a temperance man, both in principle and practice, and ably assisted his wife, who has been for many years prominent for temperance and benevolent work. No man ever came to this coast more imbued with the sterling qualities of truth, honor and human kindess and justice, and he never lowered the standard of his noble virtues.

His funeral in Oakland was largely attended on Sunday, July 13th. It was remarkable for its evidences of sincere friendship and respect on the part of intelligent men and women in all stations of life.

Death of General Fremont.

Major-General John C. Fremont died in New York on Sunday afternoon, after a sickness of brief duration. He was 77 years and six months old at the time of his death.

General Fremont's name is closely identified with the early history of California, he having been one of the most prominent figures in the events which led to its cession to the United States.

The engraving upon another page of this issue is doubtless one of the finest portraits of Fremont ever produced, and the fact that it represents him in the prime of his manhood, rather than after age had preyed upon the beauty of his countenance, will make it the more acceptable to his California friends. In connection with the portrait we give a brief sketch of his life, so full of effort and accomplishment, and so intimately interwoven into the history of the Great West.

He was born in Savannah, Ga., in 1813. In 1833, he obtained a position as teacher of mathematics in the U. S. Navy, which he kept a few years, and then went into surveying and civil engineering. In 1838-39, he accompanied M. Nicollet, a Frenchman and a distinguished man of science, in explorations of the country between the Missouri and the British line. These explorations were made under the authority of the Government, and while engaged in them in 1838, Fremont received from President Van Buren, under date of July 7th, a commission as second lieutenant in the corps of topographical engineers.

In 1842, Fremont projected a geographical survey of the territory of the United States from the Missouri river to the Pacific Ocean, the feasibility of an overland communication between the two sides of the continent being a leading idea in the scheme of explorations. He applied to the War Department for employment in this service, and having received, at his own suggestion, instructions to explore the Rocky mountains, and particularly to examine the South Pass, he left Washington, May 2, 1842, and on June 10th began his expedition from a point near the mouth of the Kansas river, a few miles beyond the Missouri border, whence he proceeded up the Platte river, through bands of hostile Indians, to the South Pass, which he carefully examined.

He next explored the Wind River mountains, the loftiest peak of which, 13,750 feet above the sea, he ascended August 15th, accompanied by four men. This mountain is now called Fremont's Peak. From the Wind River mountains, which he left August 18th, Fremont returned to his starting place by nearly the same route that he had followed going out. He reached the mouth of the Kansas October 10, 1842, after an absence of four months. He had encountered much hardship and many perils, and had successfully accomplished all the objects of the expedition. Over the whole course of his extended route, he had made barometrical observations to ascertain the elevations both of the plains and of the mountains, and astronomical observations for latitudes and longitudes.

Immediately after the publication of the report of this expedition, he planned another of a more comprehensive character. He determined to extend his explorations across the continent, and to survey the then unknown region lying between the Rocky mountains and the Pacific ocean. In May, 1843, he commenced his journey with 39 men and proceeded up the Kansas river far enough to ascertain its character, and then crossed over to the Platte, which he ascended to its source in the mountains, where the Sweetwater, one of its tributaries, springs from the neighborhood of the South Pass. He reached the pass August 8th, went through it, and saw the head waters of the Colorado flowing toward the Gulf of California. On September 6th, after travelling over 1700 miles, he came in sight of the Great Salt Lake, of which no accurate account had ever yet been given, and of which very vague and erroneous notions were entertained.

His investigations effected important rectifications in our geographical knowledge of this portion of the continent, and had subsequently a powerful influence in promoting the settlement of Utah and the Pacific States. From the Salt Lake he proceeded to the upper tributaries of the Columbia river, whose valley he descended, until on November 4th he reached Fort Vancouver, near the mouth of the Columbia. On November 10th he set out on his return to the States. He selected a southeast route leading from the lower part of the Columbia to the upper Colorado, through an almost unknown region crossed by high and rugged mountain chains. He soon encountered deep snows which impeded his progress and forced him to descend into the great basin, and presently he found himself in the depth of winter in a desert, with the prospect before him of death to his whole party from cold and hunger. By astronomical observation he found that he was in the latitude of the bay of San Francisco, but between him and the valley of California was a range of mountains covered with snows which the Indians declared no man could cross

and over which no reward could induce them to guide him.

Fremont boldly undertook the passage without a guide, and accomplished it in forty days, reaching Sutter's Fort, on the Sacramento, early in March, with his men reduced almost to skeletons, and with only 33 out of 67 horses and mules remaining, and those that survived so weak and thin that they could barely walk while led along. He resumed his journey on March 28th and got back to Kansas after an absence of 14 months.

Fremont was brevetted Captain in January, 1845, and in the spring of that year he set out on a third expedition to explore the great basin and the maritime region of California and Oregon. The summer and until October was spent in examining the head-waters of the rivers, whose source was the dividing ridge between the Pacific and the Mississippi Valley. Leaving the shores of Salt Lake in October he proceeded to explore the Sierra Nevada, and in the dead of winter again crossed the range into California for supplies. He made his way into San Joaquin valley, where, leaving his men to recruit, he went himself to Monterey to obtain from the Mexican authorities permission to proceed with his exploration. Permission was first granted and then revoked, and he was ordered to leave the country without delay. This he refused to do, as his men were in no condition to move at the time. The Mexican Governor Castro prepared to attack the 62 Americans of the party, but Fremont took up a position 30 miles from Monterey and built a rude fort, where he hoisted the American flag. No active steps were taken by either party and shortly after Fremont started up Sacramento valley for Oregon, but he was recalled by advices from Washington directing him to watch over the interests of the United States in California, there being fears that it would be turned over to England. Fremont promptly returned and the settlers flocked to his camp, and in less than a month Northern California was freed from Mexican authority. He joined the naval forces at Monterey and organized the California Battalllon, a mounted force of which he was appointed Major. He was also appointed by Commodore Stockton Military Commandant and civil Governor of the Territory. War having broken out between the United States and Mexico, he was engaged in suppressing insurrections by the Mexican inhabitants and preventing a war with the Walla Walla Indians. January 13, 1847, he concluded with the Mexicane articles of capitulation, which terminated the war in California.

A relic of these warlike times was visible until recently in the shape of a trench made by Fremont on Fort Hill, now a rich residence portion of Los Angeles and overlooking the finest business portion of the city, then a happy Mexican village.

He left for "the States" in June, 1847, and arrived in Washington in September. October 14, 1848, Fremont, at his own expense, organized an expedition to cross the continent. He had 33 men and 120 mules, and with these he made his way along the upper waters of the Rio Grande, through the country of the Utes, Apaches, Comanchee and other tribes then at war with the United States. He had resigned his position as Lieutenant-Colonel, and was no longer an officer of the Government. His object was to find a practicable passage by this route to California. In crossing the Sierras his guide lost his way and terrible suffering ensued. All of his animals and one-third of his men perished. Cannibalism was resorted to. Finally, he succeeded in retracing his steps to Santa Fe, N. M. Gathering together 30 men he made another start for California, and succeeded in reaching Sacramento in the spring of 1849.

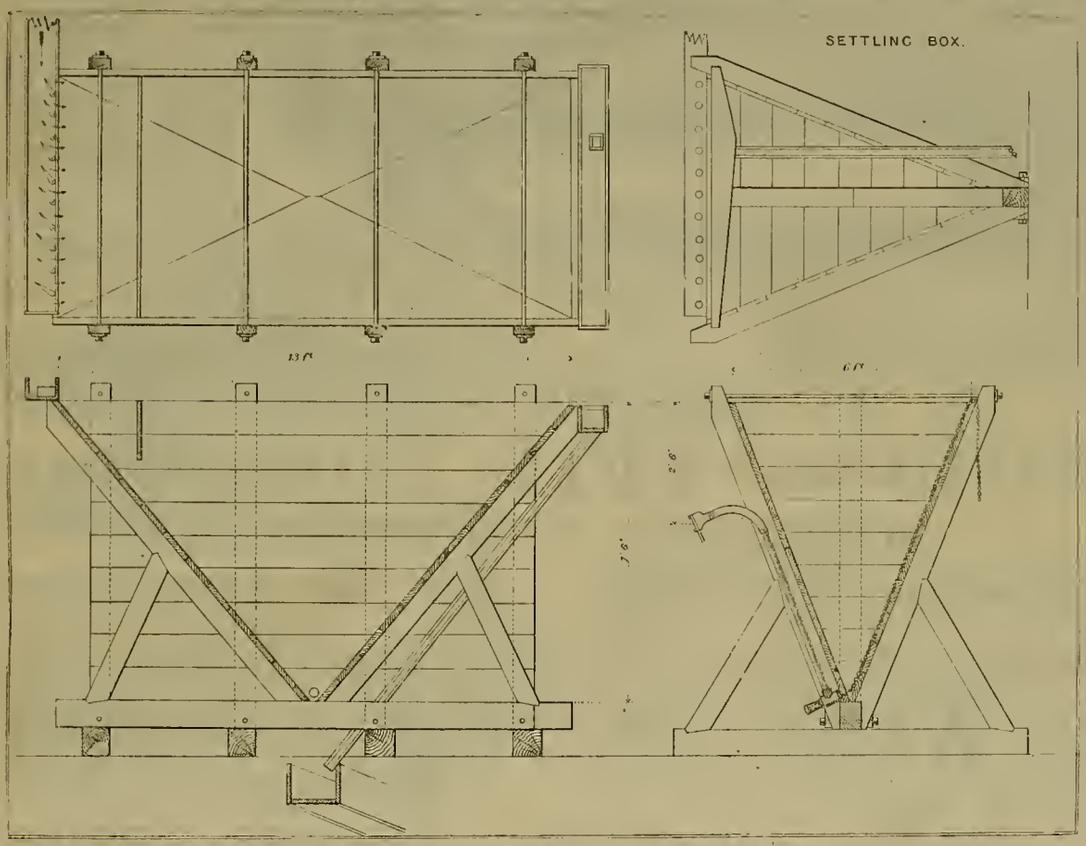
Fremont now determined to settle down in California. He had bought the Mariposa estate in 1847, and on this large tract were a number of valuable gold mines. His title to the property was contested and he was kept in litigation until 1855, when the suit was decided in his favor by the Supreme Court of the United States. In 1849, he received from President Taylor the appointment of Commissioner to run the boundary line between the United States and Mexico. In December, 1849, the Legislature of California elected him on the first ballot as one of the two Senators to represent the State in the United States Senate. He resigned his Commissionership and went to Washington by way of the Isthmus. He took his seat in the Senate September 10, 1850, the day after the admission of California as a State, and in drawing lots for the terms he drew the short term, which expired March 31, 1853.

Fremont returned to California on the first steamer that sailed after Congress had adjourned. For two years he devoted himself to his private affairs, visiting Europe in 1852. In 1852, while in the Senate, Baron Humboldt sent him "the great golden medal for progress in the sciences." A few months earlier the London Royal Geographical Society sent him the "Founders' Medal." While in Europe he learned that Congress had made an appropriation for the survey of three routes from the Mississippi valley to the Pacific, and he returned to the States immediately for the purpose of fitting out his fifth expedition on his own account. He left Paris in June, 1853, and in September was already marching across the continent. He found the pass on the line of latitude 38 and 39 degrees, reaching California in safety. For 50 days his party lived on horseflesh, and for 48 hours at a time were without food.

With such a record of travel in these unknown regions, he fairly earned the title of "The Pathfinder," which he has held so long. He was in 1856 a candidate for the Presidency of the United States, but was defeated by Buchanan. In 1858 General Fremont returned to California. When the civil war broke out General Fremont went to the front and did good service. He resigned his commission in 1862. In 1877, he was appointed Governor of Arizona by President Hayes. Since the expiration of his term of office he has lived in retirement and engaged himself in civil pursuits.

At the last session of Congress, General Fremont was placed on the retired list of the army, and then for the first time in several years began to enjoy a comfortable income. He was the author of several books detailing his work of exploration west of the Mississippi.

General Fremont was singularly fortunate in his domestic relations. In October, 1841, he married Jessie Benton, a daughter of the well-known Senator "Tom" Benton, and in her he found a true helpmeet, who ably forwarded his various plans. She is a lady of varied attainments, literary and other, and is well known in social circles in New York and Washington. She is at present in Los Angeles, in this State, with her unmarried daughter Elizabeth. Mrs. Fremont's friends will at once urge that a pension be given her, as the little she makes by her literary labors is entirely inadequate for their support. A bill has already been introduced in Congress toward that end. A movement is talked of by the Native Sons of the Golden West looking to the erection of a monument and the eventual burial of Fremont's body in Golden Gate Park, San Francisco.



POINTED SETTLING BOX FOR QUARTZ MILLS.

Settling Boxes.

The regular settling-tanks used in silver mills before pans and for retaining tailings in some places require digging out and changes of the pulp flow from one to the other; they are therefore not adapted to the purposes of a continuous working process. Where tailings are caught in large pits it is frequently seen that the settling is not so perfect as the large size employed would warrant, and this is due to the surface currents and channels cut in the deposited material when it fills to the surface. The large, pointed boxes, if properly built, are deserving of more attention than they have yet received for many purposes. Where water has to be used in part over again in a mill, a series of these boxes will do far more effective work than pits or settling-tanks, and require no attention or labor; they will deliver a small stream of thick concentrated pulp at the bottom and give an overflow of almost clear water at the top.

To make them effective, however, there are several points which must not be ignored. (1) Proper angle at the bottom to insure descent of slimes—not less than 50 degrees from the horizontal; (2) proportioning of water inflow to capacity; (3) avoiding too small a discharge opening at bottom; (4) preventing surface currents from the inflow to the overflow end; (5) preventing ingress of coarse sand, chips and other obstructing matter.

The accompanying engravings show complete details and dimensions of a large pointed box that is of sufficient size to handle the pulp and water from five or ten stamps, according to size. The cuts and description are taken from a new work published by E. and F. N. Spon, 12 Cortlandt St., N. Y., entitled "Losses in Gold Amalgamation," with notes on the concentration of gold and silver ores, by Walter McDermott and P. W. Dofield. It will be noticed that a partition extends across the box near the inflow end, dipping well down into the water, so as to cut off surface currents and insure a mixture of the incoming pulp with the whole mass of water in the box; in the absence of this, currents of muddy water will be seen flowing through the clearer mass direct to the outflow end.

A frequent mistake of millmen in making flat settling-tanks is to assume that length is all-important in settling slime, and to put in too many zigzag partitions, so as to force the water current to take as long a course as possible. This frequently destroys the very advantages sought, by making a comparatively rapid surface current in narrow channels. The proper means to insure settling is to diminish the speed of the current, not to lengthen its line course.

The capacity of the box shown will depend, of course, in the perfection to which settling has to be carried. When it is a matter for settling for pan amalgamation, the greatest care is necessary, because the chlorides and sulphides of silver are apt to be exceedingly light and flaky in form. At the Montana mine, 10 boxes of the kind shown in the cuts were put in (by Messrs. McDermott and Dofield) and received the settled discharge from 50 stamps handling 105 tons of ore daily, together with the great excess of water resulting from amalgamation, and then did excellent work with almost clean water overflow. Enough was accomplished to prove the complete efficiency of the boxes and to justify the conclusion that with proper arrangements a great improvement could be effected over the tank system of settling for pans.

Academy of Sciences.

The regular meeting of the California Academy of Sciences was held Monday evening, July 7th, President H. W. Harkness presiding.

Additions to the museum were as follows: William Barber, a live scorpion from Ross valley; Mrs. C. W. Knox, Oakland, young of canary in first plumage; L. Beldieg, Stockton, skin of least bittern; Wm. M. Willey, San Francisco, abnormal egg of chicken; E. D. Flint, Oakland, cranium of *Scalops Townsendi;* James L. Ord, Arizona, *Heloderma Suspectum,* (Gila monster), Melville Attwood, fossils from Pinmas county. Additions to the library were reported as follows: From correspondents 156, by donation 4, by purchase 25, total 185.

F. Gutzkow gave some interesting information regarding a diatomaceous earth from Sonoma county.

This mineral which is found in many places in California consists chiefly of silica and water and is of considerable economic importance. It has been used for building; as a polisher under the name of electro-silicon; in glass-making; and as an absorbent for nitro-glycerine in the manufacture of giant powder, etc. That obtained in California unfortunately has been found unfit for the manufacture of giant powder and the presence of a small quantity of iron prevents its being used for making white glass. Mr. Gutzkow stated that he had devised a cheap and efficient method of eliminating the iron; the method depends on the volatility of ferric chloride.

Prof. Carl Eigenmann then followed with an interesting talk on salmon and the salmon trout, illustrated by many specimens of each, especially the latter, secured during a recent stay at Lake Tahoe. The subject is of special interest as bearing upon troubles that have arisen between the Fish Commission and alleged violation of the law as to what really is a salmon and what a salmon trout. Both fishes belong to the genus *Salmonidæ,* which also includes the white fish and greylings.

This genus is noted for the great variability of the species, the age, season, water, food, kind of bottom, etc., producing such variations that in some cases where a large trout and a small salmon are compared it is almost impossible for any one but a scientist to distinguish between them. He had been sold a salmon trout for a salmon in the city markets, and the fisherman grew wroth at being told it was the former.

At Lake Tahoe the fishermen divide the trout caught there into seven species, but the scientist would class them all as of one species, differing somewhat in peculiarities at different ages and from local causes.

The professor stated that the trout were spawning in the lake this year, whereas they had formerly ascended the streams for that purpose, and that this might be owing to the extreme hight of the waters, or to their low temperature, but the fishermen attribute it to the intelligence of the fish. The Fish Commission has established box-traps at the mouth of the streams, in which the fish are caught as they start to the spawning ground, are stripped of their spawn to supply the hatcheries and then returned to the lake. To avoid this unnatural process, the fishermen contend, is the cause of the fish spawning in the lake.

The Pacific Coast salmon of commerce, the salmon that is used for canning, is confined to the west coast of America, though it exists also in the eastern waters of Asia. It is a deep sea fish, ascending the waters of rivers to spawn. It is the popular opinion that after depositing its spawn the fish descends again to the ocean. The lecturer gravely doubted if the salmon that ascend the fresh water streams ever again descend. Many of them heat themselves fairly to death against the rocks and pebbly bottoms in their efforts to reach the upper waters, and on many of them a fungus grows, which in cases eats holes in the skin. It is possible that those whose progress is barred by dams or falls may return to deep water.

The male salmon is readily distinguished, when caught on its up-stream journey, from its female consort, by having a hooked snout. The salmon caught in the sea never shows this peculiarity.

BOISE CITY, CAPITAL OF IDAHO.

Metropolis and by provision of Constitution Permanent Capital. Unusual opportunities for investment and business. Capital needed. Mortgages net 10 per cent. Saw mills, brick kilns, woolen mills, iron works wanted. Unlimited water power. Best society, schools, churches. Perfect climate. Stock growers' paradise. **Free Government Land.** Great grain, fruit and vegetable country. Field crops net $25 per acre. Idaho, "Gem of the Mountains," will soon be a State. Third in precious minerals. Output last year, $17,000,000.00. Combine business with pleasure and visit us. Excursion rates.

IDAHO, "GEM OF THE MOUNTAINS."

Idaho's rapid increase in late years in mineral production is due to the scientific methods formed by capital and long experience. There is large opportunity throughout the mining districts of Idaho to develop mines with almost the certainty of large profits. Gold bullion is cashed at the Government assay office in Boise City. At the same time no mining field offers more attractive inducements to the hardy miner whose capital lies chiefly in his experience and in his pick. Full and complete information concerning Idaho mines will be mailed on application.

IRRIGATING CANALS.

Another great opportunity for capital in Idaho is in large irrigation enterprises. Projects are on foot to reclaim several hundred thousand acres, but there is room for many other such projects. Idaho has abundance of water, and the profits of irrigation are large and sure.

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, July 17, 1890.

General trade continues quiet, but the outlook is favorable for a largely increased fall business.

The fall in the price of iron for prompt shipment and on the way is considered favorable to the iron manufacturing industry.

The final passage of a silver bill more favorable to the white metal than its predecessor, is accepted as a sure forerunner of more active times in the mining industry on this coast.

The money market is fairly easy, with no marked stringency looked for until after next month.

QUICKSILVER.—Receipts the past week aggregate 256 flasks, and exports by sea, 43 flasks. The market continues moderately active and firm.

MEXICAN DOLLARS—The market sbows more buying in a small way by Chinese, who fear still higher prices. It is difficult to obtain correct quotations of this market, owing to large holders being out of the market except at 90 cents, while buyers name 87½@88 cents.

SILVER—The market abroad gradually strengthened up to to-day, when there was a shading off, London being quoted at 50d. against 50 5-16d. on yesterday, and New York, $1.09 against $1.09¾ on yesterday. In our market there is very little silver offering, owing to holders believing that a much better price will be obtained in next month. As near as can be ascertained, very little if any silver can be bought here at less than $1.10, and it will take $1.15 to draw out any large quantities. Among well-informed mining men it is freely asserted that the production of silver in this country will not sbow much of an increase, probably not to exceed 1,500,000 ounces a year, even with the price advanced to $1.15 or more an ounce.

BORAX—Receipts the past week aggregate 494 ctls., and exports by sea 1001 ctls. to New York. The market is easy, but not quoted lower.

LIME—Receipts tbe past week aggregate 3465 bbls. The demand shows a slight increase.

LEAD—The market is fairly firm. The consumption in this State shows a steady increase.

TIN—Exports by sea the past week aggregate 106,250 lbs. to Santa Rosalia. The market is dull, but not quoted lower. The higher price of silver has a favorable influence on tin abroad.

COAL—Imports tbe past week aggregate as follows: Seattle, 7094 tons; Comex, 4300; Coos Bay, 700; Tacoma, 4878; Nanaimo, 667; total, 17,639 tons. The market appears to be unsettled. Buyers believe that with the strike at the Wellington mine settled, prices will shade off, while importers are inclined to the opinion that it has continued so long, the supply from that locality will not prevent the market from advancing when the winter demand sets in. The coast collieries' output is quite liberal, wbile the list of vessels loading coal for this port at Newcastle, N. S. W., and at Sydney shows a gradual increase.

COPPER—The market is strong, with the outlook favorable for continued strength. London cables report that French holders are still feeding the market. It is stated that when their boldings are closed out prices abroad will go still higher. New York mail advices report as follows: Lake Superior ingot is no longer offered at 16½ cents, and there seems to be a limit upon the quantity tbat may be obtained at 16¾ cents. The prices generally quoted are 17 cents for prompt and near luture delivereies and up to 17½ cents for distant future. Arizona is still held at 15½ cents and common casting brands at about 14¾ cents. Copper, at present tied up in litigation, can, it is said, be disposed of wlthout difficulty at prices within a fraction of those now current on the market. In point of fact, there is a standing offer of a remarkably full price for the entire amount."

IRON—English iron on passage and to load is lower. This will unquestionably affect the spot market. Consumers are buying sparingly, not caring to anticipate their wants.

20-STAMP STEAM QUARTZ MILL

With Corliss Engins.

Also 6-inch Cornish Pumping Plant with Corliss Engine; also Single Drum Hoisting Engins, Boilers and Cass, all in good repair. Apply to Room 24, 320 Sansome Street, San Francisco.

The Regan Vapor Engine Company.

Attention is called to the advertisement of this company on another page. The Regan engine has passed the experimental stage, and the large number sold (over 150) witbin a year, and now in successful operation on this coast, is as good evidence of its practical usefulness as need be offered.

Where the original purpose of this company was to supply a small power, cheap and conveninent for light requirements, it has enlarged its scope by careful steps, until now engines are being built up to as high as 60 h. p., with a prospect of being able to furnish a still greater capacity. The great economy and safety of these engines, and the almost endless use to which they are adapted, make them deserving the careful attention of all who require a motive power for any purpose. While many testimonials of satisfaction from those who have their engine in daily use are in the hands of the manufacturers, a still greater evidence of the Regan Vapor engine's merits is the fact that it has been adopted by Thos. Kane & Co. of Chicago and Racine, the largest launch builders in the United States, after having experimented for years to secure a perfect motor for their launches. A large number of engines ranging in sizes from ¾ to 60 h. p. are now in course of construction. Send for illustrated catalogue. Regan Vapor Engine Co., 221-223 First Street, San Francisco, Cal.

THE new cruiser San Francisco, built at the Union Iron Works, is on the dry-dock at Hunter's Point being cleaned preparatory to her trial tests in the Santa Barbara channel.

Assessment Notices.

GRAY EAGLE MINING COMPANY—Location of principal place of business, San Francisco, California. Location of Works, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 1st day of July, 1890, an assessment, No. 18, of 6 cents per share, was levied upon the Capital Stock of the corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, Room 11, No. 303 California Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 4th day of August, 1890, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 25th day of August, 1890, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

A. W. BARROWS, Secretary pro tem.

Office, Room 11, No. 303 California Street, San Francisco, California.

GOVER MINING COMPANY—LOCATION of principal place of business, San Francisco, California. Location of works, near Dr, town, Amador county, California.

Notice is hereby given that at a meeting of the Board of Directors held on the 14th day of July, 1890, an assessment (No. 2) of twenty-five cents (25c) per share was levied upon the capital stock of the Corporatioo, payable immediately to the Secretary, at the office of the Company, 13 and 15 Fremont street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on Wednesday, the 20th day of August, 1890, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on SAT RDAY, the 6th day of September, 1890, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

GRAY DEW, Secretary.

Office, 13 and 15 Fremont St., San Francisco, California.

DELINQUENT SALE NOTICE.

CARMELO LAND AND COAL COMPANY. Location of principal place of business, San Francisco, California; location of works, Monterey county, California.

Notice—These are delinquent upon the following described stock, on account of Assessment (No. 1) levied on the Fourth day of June, 1890, the several amounts set opposite the names of the respective shareholders, as follows:

NAMES.	NO. CERT.	NO. SH RES.	AMT.
O'Connell, Annie A	18	100	$50 00
" "	19	100	50 00
" "	20	50	25 00
Green, Wm D	26	150	75 00
Eddy, Ina I	15	100	50 00

And in accordance with law, and an order of the Board of Directors, made on the Fourth day of June, 1890, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the Company, Room 10, No. 415 Montgomery street, San Francisco, California, on SATURDAY, this Ninth (9th) day of August, 1890, at the hour of one o'clock P. M. of said day, to pay said Delinquent Assessment thereon, together with costs of advertising and expenses of sale.

W. T BAOGETT, Secretary.

Office, Room 10, No. 415 Montgomery street, San Francisco, California.

FULL POWER OBTAINED IMMEDIATELY.
The Moment Engine Ceases to Run, all Expense Stops

NO DANGER.

Horizontal, Upright and Marine Vapor Engines and Launches.

Three fourths to Fifteen Horsepower. From $175 to $1200.

Send for Our Large Illustrated Catelogue.

GEORGE HAAS, 324 Market St., Phelan Building, } SAN FRANCISCO, Feb 21, 1890. }

REGAN VAPOR ENGINE CO.—Gentlemen: The 2 H. P. Engine you put up in our factory last November, has given satisfaction beyond my exoectations. It does my work better than than those two Electric Motors did, with scarcely any expense for gas. I paid the Motor Company $25 per month for power, while the Vapor Engine has cost me but $2 per month so far. But, be it understood, I have not used the Engine as much as in summer, but the cost of motor would have been all the same, making a saving of $69 in three months. I am satisfied the Engine will pay for itself in less than two years. I use it for freezing cream, run three fans, coconaut grater, etc.
Yours truly, GEO. HAAS.

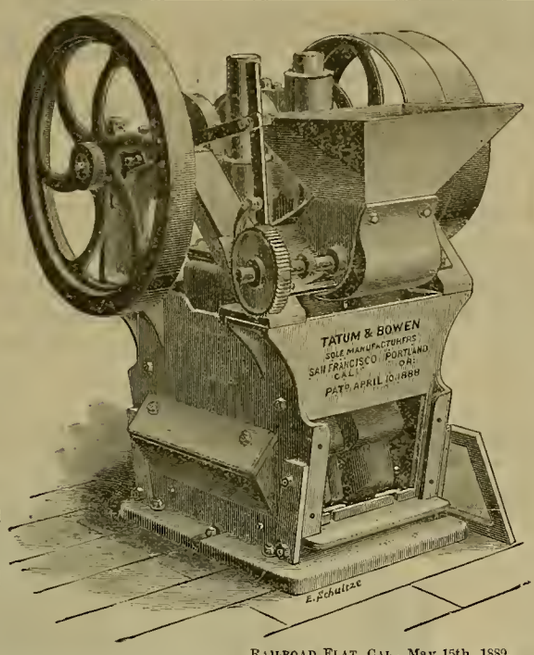
Regan Vapor Launches

The uses for small steamboats and launches are innumerable; they are convenient and serviceable for transportation, and are a source of pleasure for those who are fond of sailing. But many have been deterred from purchasing such boats, because of the trouble and inconvenience of using coal, and the necessity of obtaining a Government license, engineer, etc. Our motor does away with these objections. The small space taken up by our engine in the boat **gives more room**; the boat will seat **twice** as many persons as one the same size fitted up with a steam engine. It takes only **two minutes to get under headway**, and can be stopped when running at full speed within the length of the boat, the reverse motion being instantaneous and effective. We carry in stock six regular sizes of hulls, from 18 to 33 feet in length, our models being the best that can be obtained, and built in the strongest and most substantial manner by Thos. Kane & Co., Racine, Wis.

REGAN VAPOR ENGINE CO., 221-223 First St., San Francisco, Cal.

—THE—

PERFECTED DOUBLE Economic Quartz Mill.



Attached to each Mill is an effective

Automatic Ore Feeder.

RAILROAD FLAT, CAL., May 15th, 1889.

MESSRS. TATUM & BOWEN, San Francisco—GENTLEMEN: I have had many inquiries in regard to the performance of your oscillating Stamp Quartz Mill, to all of which I have made substantially the following answer:

That it will crush and discharge through a No. 30 mesh wire screen, 6 tons of average quartz per 24 hours; that, compared with the common stamps, the power required to do the same amount of work is considerably less—the slipping motion of the stamps reducing the ore much faster than the drop alone can; that the discharge is good, and as to amalgamating and saving gold, my experience with it is that it is just about the same as the ordinary battery.

To the above I shall add that the new Automatic Feed attached is a perfect success. It can, in a moment and without stopping, be adjusted to feed just as "high" or "low" as desired, and can be depended upon to supply the stamps with ore exactly as they need it. This is important, as it saves feeding by hand, which cannot be considered at the present day, or the purchase of a high-priced feeder.

Considered as a convenient Mill for prospecting, or for a small mine, it fills the bill.

Yours truly, [Signed] JAS. S. REYNOLDS,
Supt. New York Mine, Railroad Flat.

The Mills as we make them now are Far Superior to the one at the New York Mine.

TATUM & BOWEN,

34 and 36 FREMONT ST., SAN FRANCISCO, CAL.,
AND PORTLAND, OREGON.

MANUFACTURERS OF MINING AND SAW MILL MACHINERY.

SALT LAKE CITY!

ONE OF THE GREAT FIVE.

New York, Chicago, Denver, Salt Lake City and San Francisco.

Midway between Denver and San Francisco, 700 miles from either, with no rivals north to British Columbia or south to Old Mexico, **Salt Lake City** is destined to become one of the great **Overshadowing Commercial Centers** in the chain between New York and San Francisco.

The **recent mighty inflow** of the **best American blood** has **doubled** her population, begun the development of **untold resources**, built up **strong churches** of all leading denominations, created **charming social conditions**, fostered the public school system, **directed municipal improvements** and opened the **most profitable Business Investment, Manufacturing and Mining Opportunities ever presented** by a city that in three years will contain **over 100,000 people**, and before the end of the century several times that number.

MORE MINING CAPITAL NEEDED.

The resources of Utah as a mining region may be shown by the following from the books of the **ONTARIO SILVER MINING COMPANY, Park City, Utah** (near Salt Lake City):

Dividend paid, No 105, to April 1st, 1890, $10,850,000.00; ore and bullion sold to April 1st, 1890, $24,121,203 13. Incorporated January 1st, 1877. Capital Stock, 150,000 shares; par value of stock, $100.00 per share; market price of stock, $45.00 per share and upward. Average number of men employed, 425. Value of improvements and property (inventory December 31st, 1889), $2,985,854.77

The Company pays regular monthly dividends of $75,000.00 or 50 cents per share. Utah has numerous dividend payers on a large scale. There are many other mines that are partly developed that promise the richest returns, with sufficient capital. Within three months, coke from our own home coal (Castle Gate) has supplanted foreign coke in our lead smelters.

Salt Lake City is now one of the most delightful homes in the world, with a perfect climate, good society, churches and schools 50,000 population and growing rapidly. We will be pleased to correspond with mining men and capitalists and point the way to some specially inviting fields. We have many Mining capitalists here, who will cordially meet and aid new men. Our field is large, there is room for all. For illustrated pamphlets, summer tourist rates, and specific information, address

Real Estate Exchange,

SALT LAKE CITY, UTAH.

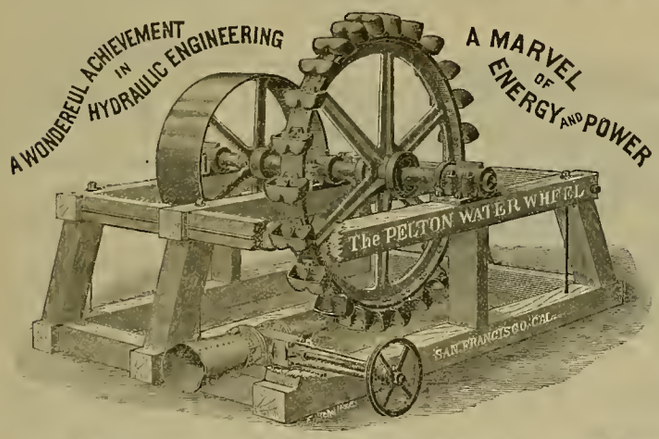
THE PELTON WATER WHEEL

GIVES THE HIGHEST EFFICIENCY OF ANY WHEEL IN THE WORLD.



A WONDERFUL ACHIEVEMENT IN HYDRAULIC ENGINEERING
A MARVEL OF ENERGY AND POWER
The PELTON WATER WHEEL
SAN FRANCISCO, CAL.

OVER 800 ALREADY IN USE.

Affords the Most Simple and Reliable Power for all Mining and Manufacturing Machinery.
Adapted to heads running from 20 up to 2,000 feet.
From 12 to 20 per cent better results guaranteed than can be produced from any other Wheel in the Country.

ELECTRIC TRANSMISSION.

Power from these Wheels can be transmitted long distances with small loss, and is now extensively used in all parts of the country for generating both power and light.

APPLICATIONS

Should state amount, and head of water, power required, and for what purpose; with approximate length of pipe; also, whether the application is with reference to *Wheels* or *Motors* described below. SEND FOR CIRCULARS.

The Pelton Water Wheel Co.
121 MAIN ST., SAN FRANCISCO, CAL.

PELTON WATER MOTORS.

Varying from the fraction of 1 up to 15 and 20-horse power. Unequaled for all light-running machinery. Warranted to develop a given amount of power with one-half the water required by any other. ☞ SEND FOR MOTOR CIRCULAR. ADDRESS AS ABOVE. ☜

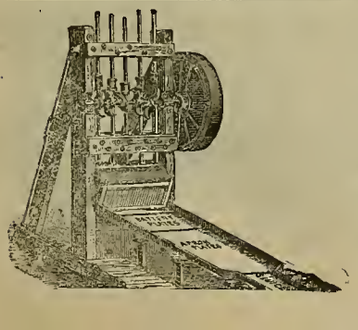
HYDRO-CARBON ASSAY FURNACES



IMPORTANT TO GOLD MINERS!

SILVER-PLATED AMALGAM PLATES for SAVING GOLD

IN QUARTZ, GRAVEL AND PLACER MINING.

PRICES GREATLY REDUCED.

Only Refined Silver and Best Copper used. Over 3000 Orders filled. Fifteen Medals Awarded. Old Mining Plates can be Replated. Old Plates Bought, or Gold Separated.

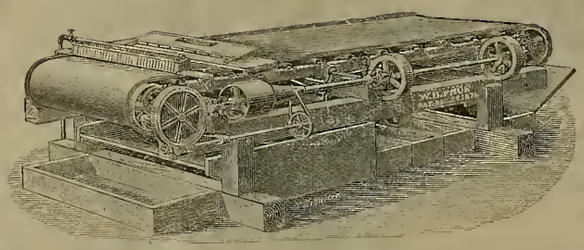
These Plates can also be purchased of JOHN TAYLOR & CO., Corner First and Mission Sts

San Francisco Gold, Silver and Nickel Plating Works, 653 & 655 Mission St., San Francisco, Cal., E. G. Denniston, Prop'r.

Our Plates have been used for 20 years. They have proved the best. We adhere strictly to contract in weight of Silver and Copper. SEND FOR CIRCULAR.

IMPROVED BELT FRUE ORE CONCENTRATOR.

The Best Ore Concentrator in the market, having double the Capacity and doing its work as close as the plain Belt machine, while its concentrations are clean. It is used in a number of Mills, the most notable of which is the Alaska M. & M. Co's Mill, where 24 Improved Belt Frues are taking the Pulp from 120 Stamps, crushing 350 tons per day, and is giving entire satisfaction as against 48 plain Belt Machines, taking the Pulp from the other 120 Stamps.



Protected by Patents December 22, 1874; September 2, 1879; April 27, 1880; March 22, 1881; February 20, 1883; September 18, 1883; July 24, 1888. Patents applied for.

There are Over 2200 Plain Belt Machines now in Use.

Price of Improved Belt Frue Vanner, $825, f. o. b.
Price of Plain Belt Frue Vanner, $575, f. o. b.

THE MONTANA COMPANY (Limited), LONDON, October 8, 1885.
DEAR SIRS:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Yours truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction that 44 additional Frues and more stamps have been purchased. ADAMS & CARTER.

Amalgam Strainers.

Bags for straining the mercury are generally made of cotton duck either sewed directly on to an iron ring as in most of the quartz mills in California and Nevada or attached to leather sewed to the ring as in some of the mills in Colorado. At the Bodie mill the bags are made of canton flannel. These bags are 10 to 12 inches in diameter at the top and from 24 to 28 inches long. They often hold as much as 1200 pounds of amalgam. The weight of the mercury is always enough to make a preliminary straining without its being touched. They are set in a hole cut in a table as shown in Fig. 1 or in boxes prepared for the purpose, which were formerly always left open but are now arranged so that they can be locked as is shown in cuts Nos. 2, 3 and 4. These we take with the description from Prof. Egleston's recent work on "The Metallurgy of Gold, Silver and Mercury in the United States."

At Judd & Crosby's mill the mercury is dipped out of the mercury receiver of the settler with a cup once in two days as it accumulates, and the plug drawn once a week to discharge the mercury, which is carried in small pails to the strainer. In the Eureka mill a canvas cloth curtain of the inside diameter of the tub is attached to the under side of the table and all nearly to the bottom of the receptacle, to prevent loss of mercury.

At the Brunswick mill all the mercury and amalgam from the settlers flow into a locked tank called a mercury safe, six feet by four feet and one foot deep, which has six feet of water on the bottom. The excess of mercury flows off by the pipe *a* (Fig. 2) in the side of the bottom of the safe, and is collected in a receiver at a lower mill. At this mill there is one box between every two settlers. The upper part has an opening just large enough for the men to pour in the mercury, but only the amalgamator opens the lid to work the amalgam. When the table (Fig. 1) is used the bags reach down nearly to the bottom of an iron vessel placed on the floor, about 18 inches high and 18 inches in diameter, set inside one 20 inches high and 20 inches in diameter. These safes were formerly made of wood as shown in Fig. 2, but as wood is always objectionable where a large quantity of mercury comes in contact with it, the top and bottom are now made of cast iron, as shown in Figs. 3 and 4. The top of the safe is placed below the siphon discharge of the settler and receives through the opening in the cover all the mercury and amalgam. The amalgam remains on the strainer. The excess of mercury runs through and flows to the mercury collecting-tank. Fig. 3 shows the ordinary safe as now constructed, and Fig. 4 one providing for the mercury, when there is likely to be an excess of it by introducing a side-opening, *a*. All the mercury and amalgam collected in the kettles from the pans and settlers are poured into this canvas strainer, which is filled nearly to the top.

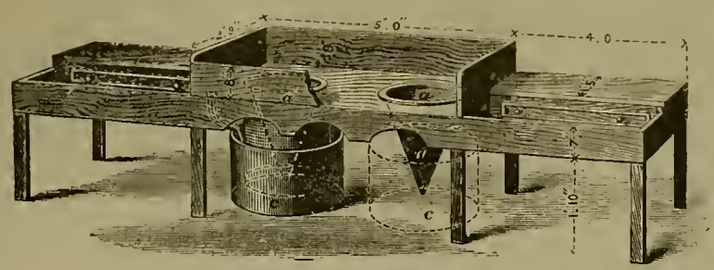

Fig. 1.—TABLE WITH BAGS FOR STRAINING MERCURY.

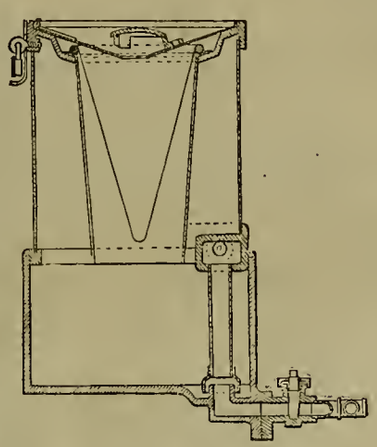

Fig. 4—QUICKSILVER AND AMALGAM SAFE.

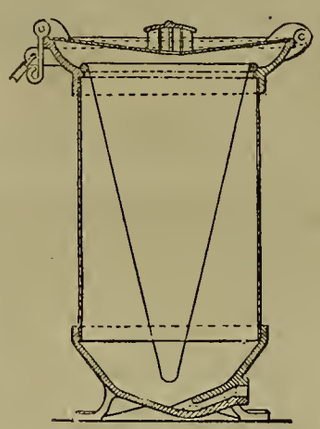

Fig. 3—IRON AMALGAM SAFE.

In some of the Comstock mills, hydraulic strainers with a pressure of 100 to 125 pounds to the square inch are used. They effect a great saving of fuel in the retorting. The ordinary amalgam from the canvas bags contains about seven parts of mercury for one of bullion, that from the press contains only 3½.

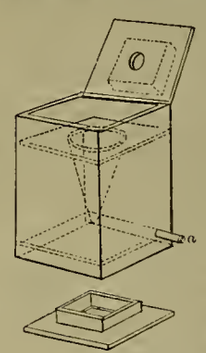

Fig. 2—WOODEN AMALGAM SAFE.

TRAIN-LOAD OF CANNED GOODS.—A. Lusk & Co. shipped a train-load of canned goods East on Wednesday. They expect to ship a full train-load of canned goods each day for the next two months to various parts of the country. This is the first time in the history of the Pacific Coast that canned goods have been sent out in train-loads.

THE MOUNT LYELL GLACIER IN THE SIERRA NEVADA.—See page 56.

CORRESPONDENCE.

We admit, unindorsed, opinions of correspondents.—EDS.

Ancient River Channels.

Ralatioua of Aurlfaroua Gravel and Lava.

EDITORS PRESS:—A vaet qnantity of matter hae heen wrltten in worke on geology ahout different epochs in the world'e history and npon the general proposition of the formation of ancient river oourees and channels. I have read a great many articlee npon minee and mining in California and eleewhere, hut there eeeme to he a lack of investigation of the particular gravel channels in which the miner is moet intereeted. It hae heen left almost entirely to the miners' explorations for what ie at present known on the enhject, on account of there being so little done hy scientiete that is of any real value to miners. Nearly each and every one of them has his own particular ideae ae to this and that formation, which leavee everything at the present time in confnslon. Now this ehonld not exiet. Nature does not go in any roundabont way in this work; everything is done in the most eimple manner, and when any of the varione eoientific facts have been learned, we find the work, whateoever it may he, is done in the eimplest manner possible, which, of oonrse, ie the heet.

Graval Mining Juat Commaucing.

We know that mining in California, and, I enppoee, elsewhere, ie in its infancy at the present time. Only those exposed parts of anoient ohannels have heen worked, where the miner with emall meane, or rather no capital except his lahor, hae heen able to carry on his enterprise. Now the aspect has ohanged. The deep, extensive, lava capped channele, nnder ridgee and tahle lands lie then in their fanoied security from the reaoh of the miner's pick and shovel. They can only be reached hy large expenditnree of oapital. They are drift diggings, and their extent is almost without limit. They are continnous and unbroken almost without exception, and when discovered, the employment to labor will he as continuoue as the coal minee of England and America. We all know the hietory of mining towns in California, which spring np almost inetantly and vanieh as quiokly. Thie is on account of the comparatively small extent of the depoeits discovered. Another thing that has given mining (that le, gravel mining) a set-hack ie that it seems that the man who oan tell the moet plauoible story, who has the most imaginative ideas that seem poseible for any one to conoeive, ie the one who is most snoceseful in getting oapital invested. Gravel mining from euch oausee has got a very "black eye." If you approach a man now-a-daye on the subject of investing in gravel mines, he will poeeibly look upon yon as a ecoundrel and trickster. It will come around all right some time, bnt things are, no donbt, in in a very had way at present.

To etart the discuseion on ae reasonable a hasie as is in our power to do, and try not to be so scientifio as to make our disonssion unintelligihle to the average miner and to etrike directly at the point whlch most interests him in hls work:

Definition of a Channal.

First, I would define a primltive river channel as one that wae made after the Sierra Nevadas were formed and hefore a lava flow oame along to fill it np. Now suppoee enoh rivers to he flowing along ae rivers flow to-day. If they oontalned gold it would be on the hottom and in the gravel as it is in onr present rivers—the gravel of the particular character of the strata over which the water flows in ite downward couree to the sea. Now after the river ia all formed and the water peacefully wending ite way down the ohannel, there comes a flow of lava from the ernption of eome voloano, whether lava ash and irregular rock taken np hy the water and carried along until it ohokee itaelf up, or whether mnd from eome fissnre, whether hot or cold or medinm hot or otherwiee. If it moved at all it would naturally flow in the primitive channel. It would hardly flow on top of some ridge; it wonld seek the lowest levels. Thie mass of lava finally solidifies, because we find it very solid now.

Lava.

Now we oome to what follows, and here let me etate that all lava with which we have anything to do contains sllica or one of the constituents of qnartz in very large qnantities, which faot alone renders the lava one of the most powerful reeistante to the action of heat, cold and the aotion of water. Most stratified rocks being less favored in that reepect are more suseoptible to the agenciee of erosion, from which canse we wonld naturally have the bed, or country rook, gradually wearing away much faster, so to speak, than lava iteelf.

Now, knowing theee facts, where should we look for the lines of the cnttinge of the new channels that wonld naturally he cnt by the dieplaced waters of the primitive ohannel? All things being equal It would evidently cnt along the line of least resietanoe whioh would aeeuredly he on either edge of the lava flow when it comee in contaot with the hed or ocuntry rock. The erosion would be generally vertioal, so to speak. The new or seoondary channels would skirt either or both edges of the lava flow. Now what kind of gravel wonld these seoondary channels naturally contain hut gravel of the character of the ocuntry rook passed over, with a large portion of lava gravel or bowldere? Thie last feature is a very valuable characteristic in determining the class of channele to whioh it belonga. Now, suppose after these secondary channels are formed there oomes

A Secoud Lava Flow,

Would not the oonrse of the second flow be along theee secondary ohannele? A fine example of theee eeoondary ohannels, lava-capped, may he fonnd on the Mooreville ridge, in Plnmae and Botte counties, a eharp ridge of grayieh lava ash in the center, with a platean of haealt ekirting it on either edge. The eame formation of different sete of channels goee on, correeponding to different lava flowe, all the eeoondary ohannels containing large qnantities of lava gravel.

Near Dogtown, in Butte oonnty, there are as many as five or six separate flows of lava, with as many different eets of channels. Occasionally we meet with channels where there has heen hut one flow of lava and the seoondary or parallel ohannele stand ae benches along adjaoent to the lava. Bnt where there ie no lava cap, the erosion hae left the channel only in epote, the bowlder deposit partially acting as a protector in place of the lava oap. The most important channels of the second class are

The Quartz Graval Chaunals,

Called so from the fact that they contain very little, lf anything, but qnartz gravel in the ohannel. There ie a very wide difference of opinion among minere as to the age of these qnartz gravel depoeits. One thing eeems to be certain—that is, that we may find lava without any quartz gravel, hut if we find any qnartz gravel we are certain to find lava in the immediate vicinity. This I ehonld say was a very important factor in determining thelr age. The lava has not followed the gravel, but the gravel skirte the lava nearly everywhere. If the lava followed the gravel, it would be today oapping the channels. The deepest or thickest lava would be over the center line of the quartz gravel deposit. But such is not the oaee. We usnally find the deepeet lava to one side of the quartz gravel. Thie may he eeen at La Porte, Plnmae county, where the lava nnder the Gihsonville ridge is mnch deeper than the hed of the qnartz ohannel. The only explanation that miners give is that the lava raieed up from the bowels of the earth and cut the channel off. Snoh an occurrence is possihle, but is highly improhahle.

The Grada

Of these qnartz ohannele oorresponds very nearly with the general grade of the adjaoent lava ridgee or tahle-lands. The reason of their containing almost exclusively quartz gravel is merely a matter of coujecture, but from the fact of their invariahle aeeociation with lava rock the qnartz is probahly from deposits of alkaline waters hlghly charged wlth silica from the lava. The most complete example of a quartz channel may he seen at Poverty Hill, Sierra oounty, in the claim of Kingdon & Judson, both rims heing exposed to view and ita couree easlly traced.

Pipe-Clay.

One very characterletio feature of these seoondary ohannele, whether lava-capped or not, is the quantity of "pipe-olay" they oontain, something very seldom, if ever, fonnd in a primitive channel in a mountainons conntry. A good example of the primitive ohannels may be seen at the Perschbacker and Indian Spring mines at Dogtown, Butte oonnty. There are a great many pointe in detail that might he shown to dietingnish these various olaeeee of leeds, but they would make the article too long. With your permieelon I will present in the near future a plan for the reeumption of hydranlio mining without injory to the rivers and lowlands.

MINER.

Oroville, Butte Co.

Vipond District, Montana.

EDITORS PRESS:—The mining property of Joseph Stnrm is under bond and lease to S. A. Barbonr, snperintendent of the Hecla mince, and H. T. Sappington of the Hecla Mercantile and Banking Oo. of Glendale.

The property is bonded for $8000, with $800 forfeit, and expires in eix months. A force of miners is being put to work to develop the property. In case of forfeiture of the bond Messrs. Barhour and Sappington receive half the ore extracted and half that already on the dnmp.

The "Lone Pine Oo." are abont to secnre the mines owned by Vipond Brothers and Joe A. Browne, and the sale is considered almost snre. We are informed that a heavy forfeit will be required.

Other partiee are very earnestly endeavoring to secure the "Faithful" mine by hond and leaee.

Should these three salee he conanmmated it will he a new era in the Vipond mining district, as all the veins are large and are now developed hevond the proepecting etage, while the three different companiee taking hold of them are all etrong and mean hnsiness.

B.

Glendale, Montana.

THE salt farms at the Great Salt Lake, Utah, made laet year 40,000 tons of aalt, of which 36,000 tons were ueed by the silver mills of Utah, Idaho and Montana.

SPOKANE FALLS, Washington, now has a mining stock exchange with 100 members.

The Gold Belt of Northern California.

Anciant Rivar Channals and Graval Daposita.

NUMBER VII.

[Written for the MINING AND SCIENTIFIC PRESS by JAMES F. TALBOTT, Blue Canyon, Placer Co.]

The North Fork divide system of gravel deposite in the gold helt extende from the South Yuba on the north to the North Fork of the American on the south, are formed hv the eame method ae thoea on the Middle Fork divide, and like them, have a common source.

Owing to the peculiar topography and formation of the Nevada ridge, eome of the gravel deposits from north to eouth, are many miles apart. The ohannel down this ridge, operating as a vaet natnral gronnd elnice, has dnmped its tailinge at the lower end ahout Nevada City and Grass Valley, and like a modern ground sluice when hlocked np in one place, the tailings find an ontlet at some other point, and thue all of the deposits on the ridge were formed.

On the north side of the South Yuha, eome distance below Onega, is an extensive gravel depoeit at Relief Hill, whioh belongs to the Moore's Flat and North Bloomfield syetem, and is not conneoted with this.

It hae been definitely shown heretofore, that the ohannel in the Shady Run ridge extends from Bogns Point to Bear Valley, and from Bear Valley through the ridge to Diamond oreek ie hnt little more then two miles, thus showing the oonneotion of the two ohannels ahout this point, and as a consequenoe, the common source of the gravel in the two ridges, and if the sonroe of the gravel, it mnst be of the gold fonnd in it.

The minute deecription of the Shady Rnn ridge wae, firet to show the source of the gold in the Dutoh Flat and Gold Run mines, and seoondly to show the certainty of rioh drift mines in the ridge, under the lava cap, the direot source from which all of the gold in this basin oame.

Gravel Dapoaita.

There are but few gravel deposits from the Shady Run ridge, prohably owing to the narrow and oonfined ohannel, whioh was rapidly filled. The principal depoeit on the weet ie that at Dutch Flat and Gold Run, which is very exteneive, commencing at Indiana Hill on the sonth, extending north and eaet ahont six milee to the upper or east end of the town of Dutoh Flat, where it ie cut off hy Bear river, hut appears to have been ountinuous np Bear river three or four miles farther, and at eome time connected with Elmore, Liberty and Lowell Hills. The main deposit of Gold Rnn and Dutoh Flat is an irregnlar basin, snrronnded on all sides hy high bedrock, exoept on the northeast at the inlet up Bear river, an outlet at Thompson's Hill on the weet into Bear river, and an ontlet at Indiana Hill on the sonth into the North Fork. The method by whloh this basin was formed, and subsequently filled up, ie accounted for in the following way, that a small lateral tribntary, unobetructed with lave, formed a junction with the main ancient river below Bogus Point, ahout Indiana Hill, and that the lava flow in the ridge at Bogns Point then extended down to or helow this junction, therehy forming a oomplete dam at thie outlet, whioh held back all of the detritue and material bronght down hy the floode from above.

The source of thie tributary being in the section of conntry above Dutoh Flat, when thoee breake oconrred at the Hogshack, on Canyon creek and Bear river, the flood waters from them followed the couree of thls tributary.

A Flood.

The gravel and detritue brought down from thoee breake and the periodical floods in time filled thie basin in places to a depth of 300 feet. The indioations are, that ahout the time the oonntry wae all filled up with this deposit from Indiana Hill to Dutch Flat, an extreme high flood occurred, probahly caneed hy one of those extensive breaks from the ridge above. This flood, ooming down with a great rush, broke through on the sonth at Indiana Hill, swept the lava and main channel away as far up as Bogne Point, and cut out Canyon creek between the gravel deposit and the lava-capped ridge, leaving everything on this eide abont ae we eee it to-day; while on the other eide to the north, theee flood-waters broke thronph the west rlm and cnt down an outlet at Thompson Hill, which left the condition of the Dutoh Flat portion more of a channel than a hasin. From Indiana Hill to the Dutch Flat minee, nearly three miles, the grade of the hedrock risee about 40 feet per mile. From the curve at Dutch Flat to the eaet the grade is more than 200 feet to the mile. These figures are obtained from actnal workings and snrvey At Indiana Hill the outlet chenuel ie not moro than 50 feet wide, with eteep-rising hedrook on either side several hundred feet high. From this point going north, the depoeit gradually widens till it attaine a width of a mile or more, where the C. P. R. R. orosees it. Thie is the Gold Rnn portion. The Dutoh Flat portion has an average width of ahont half a mile. At Indlana Hill the depoeit is emall gravel, oobble, and here and there a good-sized quartz howlder on the hedrock. Going north, in the Gold Run portion, the fine gravel on top attaine a depth of from 100 to 200 feet, interspersed in places with strata of sand and pipe-olay. Continning on into the Dutch Flat portion, the fine top depoeit decreasea in depth, till at the upper or east end of the town on the sonth rim it is only a few feet deep on top of the underlying maee of howlders. In the Dutch Flat portion the bottom deposit increases ae the top decreases, in depth, till the bottom to the depth of from 100 to 200 feet, ie snch a maes and jam of howlders there is but little spaoe for the fine gravel.

The Dutch Flat Depoalt.

As heretofore stated, the north and east part of the Dotch Flat portion of the depoeit, at the present time, has more the appearance of a channel thau a basin, as is indioated hy the high rim on the south and a oontinnous rim on the north, from the outlet on the west, along up Bear river to where the depoait is out off hy the course of the present river. For ages the flood waters ran through this channel and outlet to the west, until a heavy slide, or vast rnsh oame down and blooked up the narrow inlet, and turned Bear river into its present ohannel outside the gravel deposit. Positive evidences of this slide, or rush, are seen from the Polar Star and Southern Cross claims, all the way above, whloh show this inlet was suddenly blocked up, where masses of float bedrock, hnge, angular bowlders, chnnks of lava and all kinds of debrie are jammed together in a oonfused mase, but slightly washed or rounded by the action of water. It is posaible that when the lava dam at Bear valley was carried away, the vaet flood which followed, and out out the gorge for Bear river above—covered up the old channel below Dry creek, with 40 feet of debris, and swept away the gravel deposit that once connected Liberty and Elmore hills with Dutch Flat, blocked up this inlet and gave direction here to Bear river in its present channel. From the line of faote here presented, it is obvious this great gravel depoeit has oome from the ohannel in the Shady Run ridge, through the breake indicated, in conoection with that from the Nevada ridge through the hreak at Lowell hill. And what has heretofore been oonsidered the hub of all the mines in thie seotion of the gold belt, is hut an immense dumping gronnd (as are all of the exteneive gravel depoelts of thie character) for the debris and tailinge of the vast natural gronnd sluices whioh head in the ancient channels heneath the lava-capped ridges.

In the absence of any data on the snbjsct, some views expressed in accounting for certain exieting conditione, may seem somewhat speculative. Bat whether correct or not, the conditions and facts remain all the same, and must he accounted for in accord with the operation of universal natural laws. There is no mystery ahont it.

Tha Hydraulic Minaa.

The hydraulic mines of Gold Run and Dutch Flat are among the leading ones of thie olass in the State in richness and extent. Many millions of gold have heen taken ont of these mines, and millione remain buried in the hottom depoeit that ehonld be taken out and put in circulation. From the character of material and method of depoelt, those minee oan he worked now in no way but hy the hydraulio proces, with the improved appliances and giant powder. Many of the miners thonght good drift minee conld be opened ont, after the hydraulic mining was stopped. A great deal of prospecting has heen done, with no satisfactory reeulte. After getting back a certain distance, it ie fonnd the gold ie commingled all through the depoeit, and not concentrated on the bottom any place as it was on the ontside at some points. In early daye of mining here, the idea prevailed that a rich ohannel ran through from Indiana Hill to Thompeon Hill at Dutch Flat. In the spriog of 1852, I discovered Indiana Hill (the firet diggings struck hetween the North Fork and Bear river). My company worked the outlet channel from the break-off, abont 400 feet hack, where the gold was largely concentrated. In the eeason of 1853-54, having water ahout five months, with six men we took out $25,000 hy the old process of ground sluice, pick and shovel. While, the eame seaeon, the company adjoining us hack in the hill, working the eame way, harely made wages above their water hill (water sold for $1 per inch).

Shortly after the discovery at Indiana Hill the strike was made at Thompeon Hill, which originated the idea that a rich ohannel ran from Indiana Hill north to Dutoh Flat and Little York. The ontlet channel at Thompson Hill proved to be ahont the same as that at Indiana Hill, except in the former there was a heavy depoeit of hig howlders, and the rich pay extended farther hack into the depoeit. Subsequent workinge ehow that there is no snch channel. If there were, eeveral hundred miners wonld be working on it to-day in the richest drift mines in the State. It is evident, then, that this ie exclusively hydranlic gronnd and can be worked in no other way.

Equalizing Gradaa.

Let any commission examine the conditions here, and from the charaoter of the materiale and the forcee hy whioh it must have been deposeited, it will be apparent what a vast quantity of debrie can he held hack by some permanent obetruction. The conditions indicate that, in the first etages of the deposit, the high floode that swept over the steep grade in the Dutch Flat portion did not oarry the howlders and heavy hottom material as far as Indiana Hill, a distance of five milee. Then each anoceeding flood hullt up and widened the depoeit, thereby lessening the grade eo that the same flood force would not carry the heavy material as far as the preceding one, the lighter material being carried ahead and deposited on the top. By this method, the grade has become eqnalized

and the deposit leveled up, the heavy bottom material increasing and the lighter top decreasing in depth as the head or source is approached. A large percentage of this fine top gravel deposit appears to be of modern make, probably having its source from the big slides that occurred during the modern erosions, which are not likely to recur. It will be particularly observed here that nearly all of this fine gravel and light material on top has been washed off in former years with the old hydraulic appliances, that would be useless now on the bottom deposit of bowlders and hard, heavy material, which can be easily worked by the improved methods.

By adapting the principles involved in the natural method of deposit, as observed here, a location could be selected on the North Fork, where a permanent dam could be constructed that would retain every foot of the heavy bottom material of this extensive deposit, within the limits of ten miles from the dump; and all the lighter material passing the dam would affect the navigable streams but little, if any more than the natural wash from the plowed lands on the big ranches in a high flood season.

Protecting the Miner.

There is a great deal of talk about protection. If there is anything in this country that needs protection it is the great mining industry. Not protection from foreign pauper labor but from the Government itself. The present policy adopted by it is a monstrous wrong to an industrious class of its citizens. By a decree of its courts, they are deprived of the right to use their own rightfully acquired property. And if extended to the extreme limit, the principles laid down as a precedent by the courts to be followed for centuries regardless of changed conditions. If one class can be restrained, others can be where the results differ only in degree.

The drift and quartz miners loosen the material hundreds of feet beneath the surface, and the rancher loosens it on the surface, and it is all carried into the rivers alike. What is the difference whether the material is loosened with the pick or the plow? The Government infringes on right and justice by appropriating the public money to be used against a legitimate industry, and by its birelings in hunting down as outlaws and moonshiners a law-abiding class of its citizens. It has reversed the great republican principle upon which it was established—"the greatest good to the greatest number." It need to be the almighty *silver* dollar, now it is the snoreme $20 gold piece that moves the world. Gold is an actual necessery of life to the State, the nation and the mercantile world. Here then are millions directly interested, besides those engaged in its production, on the one side, who are to be deprived of this necessary of life, so that a few individuals in a comparatively small locality on the other side may enjoy the privilege of raising a few tons of wheat and potatoes.

To think this great mining industry has no protection—no recognized rights in our statute; an industry that sent out its product in hundreds of millions of gold, which sustained the credit and possibly preserved a united government. The Government should aid and protect the industry that laid the foundation and built up a prosperous State, that shines a bright, golden star in the firmament of her sister States.

The Great Blue Lead.

The "Great Blue Lead," according to all the writers and talkers, is found in most all of the mines as a separate and distinct lead or deposit and wherever found is invariably rich. None of them, so far as we know, have attempted to give any idea in regard to its source or account for its reputed exclusive richness. Running north and south through Nevada and Placer counties about on the course of the bedrock, near the township line between townships Ranges 10 and 11 East, and just above most of the extensive gravel deposits along here, is an extensive belt of serpentine formation from one to three miles in width. On the Middle Fork divide, the Brimstone plains is a prominent point on this formation.

As a natural result this formation gives character to the deposit below. We accordingly find this peculiar deposit of blue gravel in all of the deposits below, or to the west of the Serpentine, whereas it is not found above or east of it, which is also corroborative proof of the course of the ancient channels.

In the locality of Gold Run and Dutch Flat, just below the western border of the Serpentine, is an extensive body of this blue cemented gravel, which has been worked on and opened out, so that it can be traced continuously from Indiana hill to the upper end of the Dutch Flat portion of the deposit. The blue gravel here, as in all other localities in proximity to the Serpentine, forms the bottom strata on the bedrock, and the extent depends on the forces operating and the length of time continued, just the same as in all other deposits.

(To be Continued.)

MRS. C. W. BRICE offers the sum of $6000 in aid of astronomical research this year. The sum will be divided, and, in general, the amount devoted to a single object will not exceed $500. Precedence will be given to institutions and individuals whose work is already known through their publications. Applications are invited from astronomers of all countries, and should be made to Prof. Pickering of Harvard College, before Oct. 1, 1890, giving complete information regarding the discovered objects.

San Bernardino County.

Its Mineral and Other Resources.

NUMBER III.

[Written for the PRESS by JAMES H. CROSSMAN.]

Colton

Is an incorporated city, laying at an elevation of 976 feet. It contains about 1200 inhabitants, and is situated at the junction of two transcontinental lines of railroad, the Southern Pacific and the Santa Fe. The city is about three miles distant from the city of San Bernardino, with which it is connected with the California Southern and a motor railroad. Colton is a modern-built city of growing importance, and a rival of San Bernardino to the extent of bidding for the county seat when the new court house is ordered to be built. The business portion contains many substantial buildings of brick, marble, stone, cement and wood, of modern architecture, and many beautiful residences surrounded by luxurious gardens and lawns adorn the suburban streets. Handsome churches and commodious school buildings add to the attractions of the place. Banks and well-arranged hotels, together with a well-kept public park filled with semi-tropical flowers and shrubbery, give to the place an air of refinement and prosperity. The town is abundantly supplied with water, and the streets are broad and systematically laid out. The principal buildings consist of the Union and Gilbert and First National Bank blocks, Transcontinental and Marlborough hotels, new city hall, etc. The leading business house, the Colton cannery, employs 300 hands. There is a lumber-mill, pipe-works, feed-mill, brick-works, etc. From Slover mountain, three-quarters of a mile from town, large quantities of lime and marble are being extracted and shipped by rail to a market. Large quantities of fruit are grown, gathered, canned and shipped from this place. This town is steadily increasing in population, and bids fair in the near future of becoming one of California's most promising inland towns.

Ontario.

Owned by the Ontario Land Co., is worthy of note as the "Athens" of San Bernardino, with its college and schoolhouses, and the famous Euclid avenue and gravity street car. About 3000 acres of land are under cultivation and producing principally citrus fruits. Over 100 tons of raisins were shipped from this locality last fall and an evaporating establishment is in process of construction for handling deciduous fruits. The soil and climate are particularly adapted to the growth of oranges, lemons and prunes. The Santa Fe railroad crosses the colony.

Chino,

With a population of 200, is situated a few miles north of this town. A narrow gauge railroad connects with the Southern Pacific. The town boasts of a hotel, bank, stores, and a newspaper. Richard Gird, Esq., is the master spirit.

Banning

Is situated in San Gorgonia pass and located on the dividing line between fertility and sterility. The soil to the westward is fertile and productive; easterly, barren and sandy, it being on the borders of the desert; westerly, a luxuriant growth of vegetation; barley, wheat and fruit is seen, the latter of excellent flavor; while easterly nothing meets the eye but a sandy waste of desolation as far as can be seen. Banning has acquired quite a reputation as a sanitarium, particularly for invalids afflicted with pulmonary or bronchial diseases, which is undoubtedly owing to the dryness and purity of the atmosphere. The town supports a good hotel, churches and a school, as well as a weekly newspaper. The elevation of this place is 2000 feet, and the population numbers 600.

Beaumont,

Formerly known as San Gorgonia, is situated on the San Gorgonia Pass and contains many handsome buildings and a fine hotel. It is a flourishing town of 500 people, and a trade center for a large population of thriving and prosperous farmers in the valley. The Southern Pacific railroad passes directly through the town. Beaumont, like Banning, is noted as a health resort.

From San Bernardino we cross the summit of the San Bernardino range through Cajon Pass at an elevation of 3819 feet, entering the desert at Hesperia, a paper town, with its deserted, unfinished and unoccupied buildings; elevation, 3184. We descend into the Mojave desert proper and reach

Victor.

Altitude 2713; population 150; situated on the Mojave river. It is on the line of the California Southern railroad, 40 miles northerly from San Bernardino, 20 miles southwesterly from the Ord mountain and the mining district of that name. Victor forms a trade center and supply point for Holcomb and Bear Valley mining districts, Morongo district, North Central, Galena Camp and West camps of Silver mining district; also for Old Woman Spring district, for the Side Winder and other mines in the vicinity.

In the immediate vicinity of the town are two extensive granite quarries which are in constant operation, the rock finding a ready market in the southern portion of the State. The town contains two general merchandise stores, two stables, feed-yard, blacksmith shop, schoolhouse and church. The owner of the town site being strictly a prohibitionist, no intoxicating liquors are sold within its limits.

Oro Grande

Is on the banks of the Mojave river, 45 miles northerly from San Bernardino. It has 150 inhabitants and is a station on the California Southern railroad and forms a distributing and supply point for a large area of the surrounding mineral regions, farmers and ranchmen who cultivate land that lies on the borders of the river. There are lime quarries in operation in the vicinity, the product of which is forwarded by rail to San Bernardino and Los Angeles, Arizona and Lower California. Two large double patent kilns are in constant operation, giving employment to quite a number of men. The adjacent foothills and low ranges of mountains within a radius of from 10 to 12 miles have long been known to contain large and valuable veins containing the ores of gold, silver and lead, which, owing to their accompanying bases, rendered them so rebellious that they could not be profitably reduced by the free-milling process. A modern ten-stamp mill was erected on the banks of the river, using its water for power to reduce these ores. It proved a failure, notwithstanding the richness of the ore, and the mill now lies idle. It is reported, however, that a 50-ton smelter is in process of construction, which, with the rich silver-lead ores in the vicinity as a flux, will soon remedy the evil and give employment to a large number of men. The town contains the usual number of hotels, supply stores, stables, blacksmith and wagon shops, with a neat church and schoolhouse. Many small, well-cultivated farms surround the town. A ditch from the Mojave river carrying 1500 inches of water affords 30 feet of pressure head at the outlet for machinery purpose.

Barstow.

The elevation of this place above tide-water is 2105 feet. It is situated at the junction of the Atlantic and Pacific, with the California Southern railroad on the Mojave river. It is a thriving business town and contains about 100 inhabitants. There is a large and commodious railroad hotel and eating-house, a well-built depot, round-house and repair shop, and several restaurants and supply stores, which have a good local trade. Water is easily obtained from the Mojave river upon whose southerly banks the town is situated. There are quite a number of silver-lead mines in the vicinity that would be tributary to this point, should reduction works be erected. A survey line has been run from the present terminus of the Utah Southern to this place, for the purpose of forming a junction with the A. & P. R. R. Should this road be completed there could be no better locality for an extensive smelting plant to be established on the same principle as that of Hill's in Colorado. In that event the Carson & Colorado R. R. would form a junction with the U. S. R. R. at Leach's Point, in the desert, and as a feeder supply the main trunk. This line of road would pass through the heart of the desert regions of San Bernardino, which we have in brief, and will show in detail possesses immense stores of mineral wealth.

Daggett

(Altitude, 2002; population, 250) is situated at a point near the Mojave river, 85 miles northerly from the city of San Bernardino, on the line of the Atlantic & Pacific R. R., which forms a junction with the California Southern at Barstow, and with the Southern Pacific at Mojave. It is the receiving and distributing point for that immense area of desert mineral land that lays to the north, east and west. The silver and borate mines of Calico are celebrated for their richness. These mines are practically inexhaustible, and form the Comstock of the desert regions. Ord Mountain, with copper and gold, the lava beds of silver-lead and silver, Alvord, Solo, Silver Lake, Resting Springs districts and, in fact, the whole of the southern portion of the Death Valley region, are at present tributary to this town, it being the terminal point from which mail matter is made up and distributed to the numerous interior post-offices. Among the most prominent of Daggett's enterprising men is J. B. Osborne. To him is due the credit of having accomplished more toward the development of the mines in the desert region, than any other man in the southern portion of the State. He is a large mine-owner, a heavy operator and an inventor of no small capacity. Seeing the necessity for means of transportation over the barren and sandy waste of this desert region, other than by freight trains, he has recently invented a "self-propelling wagon" for transporting ores and supplies to and from such mining property as is remote from railroad facilities, thereby avoiding the necessity and heavy expense attendant upon the employment of mule teams. This steam wagon, at an early date, will be in full operation. The commission and forwarding house of Earl & Co. are an omnipresent figure, and form an important adjunct to the business portion of this as well as all frontier towns and mining camps in the State. Postmaster and County Supervisor J. A. Johnson, in addition to his duties of receiving and distributing the mail, administers the solid necessaries of life to a large area of the surrounding mining country from a varied and extensive stock of goods. Twaddle & Pueltz are also numbered among the live business men of this thriving town, carrying a large and extensive assortment of goods. There are in addition two other supply stores and first-class hotels, two wagon and blacksmith shops, two livery stables, a schoolhouse, a wholesale and retail butchering establishment, four saloons, drug store, town hall, etc., that go to the make-up of a first-class country town. Large quantities of crude borax are daily shipped from this point, the product of the celebrated mines of Coleman & Co., in the Calico mountains, 12 miles northerly from the railroad. Between this place and the Needles, on the Colorado river, there are 17 stations or section-houses on the line of the A. & P. R. R., but as trade centers they are of little importance.

Calico

Is situated in the Calico range of mountains seven miles in a northerly direction from Daggett. It has a population of 300. The discovery of silver in 1881 attracted a crowd of prospectors and adventurers. Its growth, however, at first was slow, as but little confidence was placed in the permanence of the mines and stability of the camp. The ores, though rich, free-milling and in abundance, were believed by many to be blanket ledges that did not "go to the deep." The work of development was done with that understanding, but soon confidence was restored by deeper explorations and the ores found in place and in vein-shaped fissures. In 1882, the town rapidly increased in size and population. Corner lots were in demand; business buildings and residences were erected with the usual accompaniments of all frontier prosperous mining towns. The population at that time numbered 800 to 1000.

Fortunes were realized and as rapidly lost. The fire fiend since that has attacked the town several times. The last fire of importance occoured in 1888, leaving the Calico a black smoking mass of ruins. It is now being rebuilt in a more substantial manner. The material in use is a natural cement and coarse rock forming a grit that is found in the vicinity, rendering it perfectly fire-proof. Cut stone is also used for fronts. Judge Walsh, Ex-Governor John Daggett, W. H. Stow, Dr. A. R. Rhea, Robert Gribben, J. W. Gashwiler, H. B. Stevens, H. R. Gregory, Col. H. H. Markham, William Raymond, John S. Doe and others were, in its days of prosperity, identified with its interests and many of them still remain. It is estimated that during the past nine years the yield of the mines of Calico Mountain has been at least $10,000,000, and it is still largely productive. A noted feature of this camp is that capital has never lent a helping hand. The mines have paid for their own development with large surplus as dividends.

The town at date contains five general merchandise and variety stores, four saloons, three lodging-houses, three livery stables.

Bagdad

Is a station on the line of the Atlantic & Pacific R. R., and contains a population of about 50 with a surrounding country rich in mineral wealth. The ores of gold, silver and copper abound, but the absence of water and the lack of fuel prevents developments.

Needles

Is directly tributary to California for its supplies. Being situated on the banks of the Colorado river, it is doubly favored by not only having the advantages of water transportation by a regular line of steamers on the Colorado river but railroad facilities as well. The Atlantic & Pacific railroad of the Atchison, Topeka & Santa Fe system passes through this town, and since its completion it has had a rapid growth. The population at date numbers over 600 souls. It contains several public buildings, church, schoolhouse, public hall, six variety and one merchandise store, residences and last but not least, a weekly newspaper edited and published by its proprietor, Dr. J. P. Booth. An extensive area of valuable mineral country is tributary to this town. In a westerly direction large bodies of low-grade silver-lead ores in the form of carbonates and oxides abound; while a strip several miles in width and 40 miles in length bordering the river is rich in silver and gold, on which several mineral districts have been formed. The town is destined at no distant day to be a place of considerable importance. Messrs. Monahan & Murphy are the leading spirits of the town, and have contributed largely to its growth.

(To be Continued.)

THE NORTH BLOOMFIELD MINING CO. has given notice of intention to enjoin the Sheriff's sale of its property on the judgment obtained by the county of Yuba against it for the non-payment of a fine imposed upon the company for violating an injunction to restrain it from mining by the hydraulic process. The company contends that its property cannot be sold under a judgment obtained in that manner.

PASTEUR'S TREATMENT.—In the past three years Pasteur treated 7893 persons bitten by mad dogs and only 53 died. The usual percentage of deaths is 15 90, so that Pasteur would seem to have saved 1265 lives.

THE United States Branch Mint, in this city, is again open for the receipt of bullion, the annual settlement having been made.

A LEDGE showing a little gold has been found in Murray township, Alameda county.

THE Drum Lummon mine, Montana, is making a profit of about $40,000 a month.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Alameda.

MANGANESE.—Livermore *Herald*, July 17: The first carload of manganese from the Hayes mine on Corral Hollow creek went to the city from Ellis station yesterday. The ore will he shipped for the present at the rate of two carloads a week. This output will he increased soon. Three men are now employed at the mine, and three in hauling ore. A gentleman named McClaren of Oakland has purchased of J. W. Hampton and J. P. Smith the latter's manganese claim on the east side of Corral Hollow creek, ahout three miles above the Eureka coal mine. We understand that the purchaser has let to J. W. Merchant a contract to build a road down to the creek, and up the Lawlor ridge road, and haul out to Livermore 100 tons of ore. Also that work will he begun ahout the first of August.

CHROME.—Two men are now employed at each of the three Chrome mines on Cedar mountain.

Amador.

VOLCANO GRAVEL.—Amador *Ledger*, July 19 C. H. Hoffman, president of the Volcano Gold Gravel Mining Co., came down from Volcano Tuesday. They have just finished cleaning up on the tunnel company's claim. The output fell short of anticipations, although we understand an improvement upon past years. There is quite a stir in San Francisco, especially among the wholesale merchants, in regard to the Clinton Con. property. Many of these business men have taken stock in this venture. A company store is being erected on the ground, for the convenience of employes and settlers. The contract to sink the north shaft of the Kennedy 300 feet deeper, has heen let to a party of nine miners. They are making rapid progress. In one week they put in five sets of timher, representing 25 feet of sinking. The ten-stamp mill on the McKenzie mine near Clinton is expected to start up early next week.

SUTTER CREEK.—Sinking at the Nortb Star is rapidly drawing to a close. They have reached a depth of 940 feet, leaving only about 60 feet to sink, when drifting will be commenced. In all probability this will be the end of sinking, unless something is encountered in drifting. A thorough exploration by drifting, however, will be undertaken before the property will be given up, and it is expected that nearly a year will elapse before they will be satisfied. The miners at the Rose mine are laying off for a few days, on account of striking water and not having the hoisting machinery in running order yet. In a few days, however, everything will he in position, and the water taken out by means of buckets. Superintendent Poundstone is resolved to pursue a conservative course in regard to this mine, and will give it a thorough prospecting hefore taking any steps toward the erection of a mill. The Lincoln is running along in its usual way. The mill is kept running steadily and the ore is reported to be of fair quality.

Calaveras.

MURPHY'S.—Cor. Calaveras *Prospect*, July 16: Mining matters never looked in a more healthy condition than at present, and it would seem as if success is assured to at least two mines in our midst. Bonds have been given to two parties of mines in this neighhorhood, and work on them will soon commence. Prospecting has been renewed, and a more active interest is noticeable on all sides in mining enterprises. A rich gravel strike is reported in the Cataract & Wide West mine in Eho, on the Stanislaus. Work has heen stopped in the tunnels, it is said to secure control of the property. The Total Wreck mill is completed, and is now running on quartz taken from the hottom of the shaft, about 150 feet deep. Another hoiler was added recently to the one at the shaft, and no difficulty is now anticipated in sinking to a great depth. The splendid mill, now in course of construction on the Norfolk mine, is nearing completion. In a few weeks its 15 stamps and two Tustin pulverizers will be heard pulverizing Norfolk quartz.

THE SPINOLLA.—Messrs. Agostini, Spinolla and Gamas are engaged in removing machinery from the Ilex mine to their mining property, as above. Their intention is to prosecute work vigorously at once.

THE WYLLIE & LEONARD.—G. Wbeelock, of Cave City, is engaged repairing the old arastras at this mine, on Murray creek, a little above Culhertson's ranch.

PINE LOG MINE.—*Citizen*, July 19: At the Pine Log mine, New Jerusalem, near Copperopolis, progress is being made on the mill now in course of erection. Everything is being huilt in a substantial manner for permanent business, and extra room made on the mill-site for more stamps as necessary. Mr. Vietong, the superintendent, heing an experienced quartz miner and business man, is very much pleased with the abundance of good ore that can be obtained easily on the claims which he has in charge and hopes to have the mill running in a few weeks. But his lucky find capped the climax. While taking down the old mill, there was found under the batteries and sluices enough amalgam to pay for the lumber for the new mill, estimated somewhere near $1000.

El Dorado

OAK.—*Mountain Democrat*, July 19: Henry Zumwalt was down from the Oak mine, Indian Diggings, on Monday, for material, The new mill is framed ready to be put up, and work will at once he pushed on getting the structure ready.

Inyo.

MODOCK WEALTH.—Inyo *Index*, July 16: Frank Fitzgerald, lessee and manager of the company mines at Modock, was in town Sunday. He informs us that the ore shipment for the month of June amounted to $6070 71. A single carload shipped by a chlorider paid $1736.36.

BORAX.—We are informed hy Mr. Trudo that that they will commence to haul borax out to Alvord in a short time, as the pack train to Cerro Gordo has heen hauled off. J. H. Roberts will not commence to put up his works hefore the bot weather is over. Then we shall expect to see large shipments of borax from Saline Valley.

GALENA.—Inyo *Independent*, July 19: When P. Key and A. J. Davis were taking out galena ore recently at the White Hills they encountered a vein of ore of unusual character. It is not crystallized like galena, nor is it so heavy. It is hrittle, fine-grained, has dark luster and very dark color. It was thought to he worthless, and several tons were thrown down the mountain. As a matter of curiosity a sample of the ore was sent to Mr. J. A. McKenzie, at Darwin, for assay. Mr. McKenzie replied that he found the ore contained 772.30 ounces silver per ton. He thinks that it also contains gold, and reported that he would assay for that metal. Key & Davis are not throwing any more of the ore down the mountain. It is not yet known how extensive the ledge may he.

Nevada.

SHAMROCK MINE.—Grass Valley *Union*, July 17: The Shamrock quartz mine, located helow Forest Springs and owned hy Patrick Riley and John M. Thomas, has been honded for eight months to Illinoisans, represented hy R. S. Raw, who has made all arrangements for the commencement of work, and will at once proceed to the erection of steam hoisting and pumping machinery. The Shamrock is a location of 1500 feet, held under U. S. patent. The original owners were James Harrigan and John Tierney, who had light machinery on the claim some 12 or 15 years ago. The prospects were then good, hut the machinery was too light to contend with the water encountered, and the owners were not ahle to put up a more expensive plant, and work was discontinued. The Shamrock is on the same quartz system as the Slate Range and the Noramhagua mines, and is regarded as a good "prospect."

GOLD HILL.—Work at the Gold Hill mine is progressing favorahly under the immediate direction of James Burke, one of the most experienced miners in the district. The incline shaft near the surface is hadly caved, owing to one incline heing constructed over another to make an even grade, and the long time in which the shaft has heen out of use has caused a caving of the ground and a necessity for reconstructing the upper portion of the incline.

MANHATTAN. — The machinery and material having been delivered, the work of erecting hoisting and pumping plant on the Manhattan mine, Gold Flat, will be commenced. Supt. Elliott, who went up to Nevada City yesterday to conduct the operations of constructing, says the work will be pushed as rapidly as possihle, and that he is confident that everything will he in readiness to commence forking the water hy the 1st of August.

THE DERBEC MINE.—*Transcript*, June 21: A gentleman who recently inspected the Derhec drift mine says that it is in fine condition, and there is an immense amount of gravel in sight which looks well. New ground is heing opened all the time, and the prospect is good for paying seven or eight dividends per year for several years to come. This property has yielded over $1,500,000 since work was first commenced, and yet little more is heard about it than if it were a non-working and non-dividend property. There are over 100 men constantly employed, and with the exception of the Idaho quartz mine, the Derhec employs more men, yields more gold and pays more dividends than any other mine in this section of the State. All the stockholders of it reside in San Francisco, and the stock is held by so few persons that but little is said or known about it.

NORTH BANNER.—*Tidings*, July 19: The output of the North Banner mine this month will be, it is stated, between $12,000 and $15,000, and the expenses under $4000. Thirty-eight men are employed.

Placer.

A BIG ENTERPRISE.—*Herald*, July 19: Under the direction of C. P. Udell, work has been resumed in a small way on the big tunnel being run by the Muir Tunnel and Cons. Mining Co. at Michigan Bluff. This enterprise was started some years ago, but for reasons best known to the company has been holding fire. A number of channels lies in the divide through which this tunnel is directed, and it is proposed, on the principle of the Sutro tunnel, to drain them and open them all hy means of this one hig outlet. The enterprise is one that will require a good deal of money to prosecute. Its success, however, would not only contribute largely to the gold output of the county, hut would restore to Michigan Bluff, near which town the tunnel has its opening, the life and prosperity that belonged to it in early days.

RICH PICKINGS.—We learn from O. J. Spencer of Iowa Hill, who was in Auburn early in the week, that last Saturday and Sunday there was picked from the hedrock of a mine near the Hill, which Sprague and others are working, 168 ounces of gold, the chunks varying from 15 ounces down. This does not look as though mining was played out, as some pretend to helieve.

Plumas.

GREEN MOUNTAIN. — Greenville *Bulletin*, July 19: We are credibly informed that the Green Mountain mine was turned over to G. P. Cornell on Monday last. This important mining property has been tied up in litigation more than three years, much to the detriment of the stockholders and the prosperity of this part of the county. Connected with the mine is a 60-stamp mill. The lower tunnel is into the mountain nearly a mile, and taps it at a depth of about 1800 feet. During the progress of this tunnel on the main quartz vein, much fine ore was extracted and a great deal of money obtained. The country on either side of the tunnel is unexplored, there not being a crosscut the entire length. A great deal more importance attaches to this move, from the fact that Mr. Cornell has control, also, of the cluster of mines beyond the face of the Green Mountain tunnel and lying on top and on the western slope of the mountain. This includes the Ano, Altoona, Kettle, Caledonia, etc. The Altoona is owned by Judge Emmons, who operated it last year on a small scale, hauling the ore a long distance and leasing a mill to crush it. The ore vein is large and the owner informs us that it yielded him a handsome profit, notwithstanding the disadvantages under which he operated the mine. Tapped at great depth hy the Green Mountain tunnel, this property would, no douht, yield rich returns. The same is true of the Kettle and the Caledonia, both of which were operated years ago, through shafts, the former paying, we are informed by an old miner, from $12 to $18 per ton, for a period of nearly two years. The ore was hoisted and drawn nearly a mile for crushing. All of these properties combined will make a hig mining proposition, and a consolidation we helieve to be the proper step to take. The *Bulletin* has always maintained that the Cherokee properties should be operated in connection with the Green Mountain. This proposition has found support in New York and in Plumas. If these properties are rehahilitated and the proper amount of capital enlisted, as now seems probable, much good will accrue to Plumas Co., and to Indian Valley in particular.

Shasta.

PAYING.—Redding *Free Press*, July 19: The Banghart mine on Mad Mule, recently purchased hy Bauder & Fleming, is said to be a piece of well-paying property. A gentleman told us that last May he saw two nuggets weighing over a pound each that were taken out of the mine, and in one day the owner took out $1600. The Meade boys and Bill Wilson are negotiating the sale of their mining property located on the Shasta divide. Work was prosecuted on it all last winter, a shaft having been sunk to the depth of 45 feet. At the hottom of the shaft the ledge is five feet wide, showing well in free gold.

CASTLE PEAK.—A. J. Rex, who is working for Mr. Connor, owner of the Castle Peak and Sky Blue mines, showed us some specimens Thursday that were taken from a new strike on Castle Peak ground. The ore appears to be very rich, being freely sprinkled with coarse gold. The strike was made on Monday, and it now looks as if Mr. Connor has the richest thing in the county, having three mines on any one of which a man can make $15 a day with a hand mortar.

IRON MOUNTAIN.—Shasta *Courier*, July 19: James Sallee has gone East in the interest of the Iron Mountain mines. During his absence the mine will be in charge of Jas. L. Richardson. We understand a wealthy Eastern company are negotiating for an interest in these valuable mines.

San Diego.

THE EAGLE MINE GONE.—Julian *Sentinel*, July 19: The Eagle mine has heen owned for years by Mallock & Crase. Considerable development work has been done on it, but the owners heing poor men they were not able to work it extensively. It joins the High Peak, spoken of last week as the property of Messrs. Frost & Burnett. These gentlemen are so well pleased with the way things are "panning out" up here that they have honded the Eagle for $6000 and expect to commence development work as soon as suitable arrangements can be made. Thus the old claims that have lain idle for years are passing into hands of men with capital and enterprise, and as the result the camp will soon be turning out more hullion than in its palmiest days.

Trinity.

CANYON CREEK.—Trinity *Journal*, July 19: The owners of the Fisher Gulch have a shaft down 40 feet. The ledge is from 20 inches to three feet wide and is good milling ore. Grigsby's Buck's Ranch mine was next visited. Six men are at work on this property. The shaft that gave flattering prospects had to be ahandoned on account of water coming in and making the sinking of it too expensive. Mr. Grigsby is now running a tunnel to tap the ledge under the shaft at a depth of about 35 feet. The ore in the ledge is quite rich, and a good clean-up is expected as soon as a run on it can he made with the improved arastra that Mr. Grigsby has in good working order. At the upper side of Buck's Ranch a ledge has heen cut that measures from 13 to 14 feet hut is low grade. It will probahly mill $5 or $6 per ton, and as it is very easy to work, it will probably pay well if machinery is ever put on it. A good water right and plenty of wood makes the location for a mine an excellent one. The ledge runs from 4½ to 14 feet in width. Mr. Grigshy says he can crush about 6 tons a day in his arastra which he will start up next week. Boyce & Eligh are doing some work on their ledge which shows up pretty well. They have just started a tunnel commencing where the ledge crops out on the hillside. After leaving the Buck Ranch country we took a circle around the mountain to the location of Carlson, Benjamin & Hutchins. We finally landed about 100 feet below the tunnel that is being run on the above named mine. They expect to complete the tunnel in about ten days that will tap the ledge between 50 and 75 feet. A little more tug-of-war with the brush and we arrived at the Bailey mine, owned by Bailey, Smith & Flowers. They now have the tunnel within about 25 feet of where they expect to tap the second ledge. If struck here, and there is very little doubt about the matter, the depth will be very near 300 feet, and as the ledges are from four to seven feet, this would give them an immense amount of stope. They have three ledges, but the lower one has been developed but very little. We learned from Mr. Grigsby that the Whitten Brothers of Napa had discovered several ledges above Buck's Ranch and last Saturday made four locations over the ridge into the head of Owen's creek, which empties into Steuart's Fork. The quartz they brought to camp, Mr. G. said, was very rich and the brothers were very much excited over their find. There seems to be no reason to doubt that ledges will, before long, he found near the head waters of Rush creek, East Weaver creek and on this side of Bally. When such a thing is done, old Weaver will boom.

A NEW STRIKE.—*Journal*, July 19: M. R. Newman informs us that the Brown Bear Mining Co. has made a new strike in the Coon Dog ledge. The ore on the surface was not rich, hut the company ran a tunnel to tap the ledge at a considerable depth. The tunnel cut the ledge this week and a good hody of ore was disclosed. The company is taking out $80 rock from the ledge.

Tuolumne.

SULPHURETS.—Tuolumne *Independent*, July 16: The Golden Gate sulphurets are now being shipped to and worked at Angels Camp. Heretofore the ore has heen worked at the Sonora reduction works, but owing to some misunderstanding between Mr. Maltman and Mr. Fiscber, the former has refused to have anything to do with the sulphurets.

NEVADA.

Washoe District.

ORE AND BULLION YIELD.—Virginia *Chronicle*, July 19: This week's ore yield of Comstock mines aggregated 7473 tons divided as follows: Consolidated California & Virginia, 2749 tons, assay value $16.50 per ton; Savage, 448 tons, assay value, $23.60 per ton; Hale & Norcross, 1036 tons, assay value, $16.61; Yellow Jacket, 490 tons, assay value, $21.75; Crown Point, 850 tons, assay value, $16.17; Justice, 196 tons, assay value, $29.87; Alta, 340 tons, assay value, $20.50; Overman, 480 tons, assay value, $22.50; Chollar, 522 tons, assay value, $19 27; Belcher, 362 tons, assay value, $19.66. Following was the hullion yield of the ore product from each of the above mines, estimated on the probability that 80 per cent of the value of hattery sample pulp assays was returned: Con. Cal. & Va., $37,000; Savage, $8,500; Hale & Norcross, $14,600; Chollar, $8150; Yellow Jacket, $8500; Crown Point, $11,500; Overman, $8600; Alta, $5500; Justice, $4.800; Belcher, $7,100. Total, $114,250.

SIERRA NEVADA. — On the 630 level the west crosscut from the southwest drift, 60 feet from the shaft station, is advanced 436 feet. At a point 16 feet from the face of this crosscut a north drift is advanced 45 feet in quartz, clay and porphyry, showing low assay value.

UNION CON.—On the 1465 level from the north lateral drift, opposite west crosscut No. 4, east crosscut No. 1 is in porphyry, carrying some water.

MEXICAN.—On the 1465 level, at a point 70 feet south from west crosscut No. 4, west crosscut No. 5 is advanced 229 feet, continuing in porphyry showing some clay.

OPHIR.—On the 1300 level, the winze at a point 66 feet southwest of the raise is down 87 feet, continuing in low-grade quartz.

CON. CAL. & VA.—The 1300 and 1500 levels continue to yield the usual quantity of ore. Shipped to the Morgan mill 1699 tons and 520 pounds of ore, and to the Eureka 1649 tons and 1550 pounds, battery sample assays showing an average value of $16.50 per ton (2749 tons milled). Shipped hullion valued at $12,630.90 to the Carson mint.

BEST & BELCHER.—On the 1200 level west crosscut No. 1 is extended 81 feet. Formation, porphyry, clay and quartz showing some value.

GOULD & CURRY.—On the 625 level, all work is still confined to repairing south drift.

SCORPION.—The southwest drift from the 660 level shaft station is advanced 690 feet, and continues in clay and porphyry.

ANDES.—On the 420 level the north drift from west crosscut No. 2 is in 77 feet; formation, quartz, clay and porphyry, giving low assays.

SAVAGE.—Shipped 448 tons of ore, showing an average value of $23.60 by battery sample assays. The 1300 level north drift is in 110 feet and continues in good ore. There are 7 sets of timbers in place following the ore. Extracting ore from the 300 to the 1300 level. No change in explorations at other points. Bullion on hand valued at $14,000.

HALE & NORCROSS.—Shipped 1036 tons of ore during the week, showing an average value of $16.61 per ton by battery sample assays. Bullion on hand on July account valued at about $10,000.

WARD COMBINATION SHAFT.—The 1800 level east drift is advanced 436 feet and the west 388. Both are in porphyry.

CHOLLAR.—Extracted 522 tons of ore, battery sample assays showing a value of $19.27 per ton.

POTOSI.—The 930 level east drift from the winze is in 32 feet from the footwall and has reached what is believed to he the hanging-wall of the vein. The material passed through was porphyry and fair-grade ore. Cutting out a station on the 1030 level is being pushed to completion.

ALPHA.—The 600 level southwest crosscut is in 71 feet, the face in quartz and clay. East crosscut No. 2, same level, is in 37 feet, face in quartz and porphyry.

EXCHEQUER.—The 500 level east crosscut is in 82 feet, the face in clay and porphyry. The 600 level north lateral drift is out 396 feet; face in porphyry and quartz.

CON. NEW YORK.—The north drift from the top of the raise above the 800 level is out 307 feet, the face in porphyry.

YELLOW JACKET.—Shipped 490 tons of ore showing average assay value of $21.75 by battery sample assays.

CROWN POINT.—Shipped during the week 850 tons of ore showing an average value of $16.17 per ton hy pulp assays.

CONFIDENCE AND CHALLENGE.—Joint imperial west crosscut No. 2, 1000 level is in 222 feet, face in quartz.

BELCHER.—Have started a stope in the 1000 level south crosscut and have opened two sets wide in ore. Shipped during the week 362 tons of ore showing a value of $19.66 per ton by battery sample assays.

SEG. BELCHER.—The raise above the 1000 level east crosscut No. 1 is up 177 feet, the top continuing in low-grade quartz. Have discontinued work in the top and started sinking a winze below the 1300 level directly under raise No. 1 above that level.

JUSTICE.—During the week crushed 196 tons of ore showing a value of $29 87 per ton by battery sample assays.

ALTA.—The ore output this week was 340 tons, showing an average assay value of $20.50 per ton by pulp assays.

OVERMAN.—Shipped 480 tons of ore during the week showing an average value of $22 50 per ton by battery sample assays.

UTAH.—On the 725 level at a point in the south drift, 130 feet from the main north drift, west crosscut No. 1 is advanced 69 feet and has reached the footwall. The formation passed through was porphyry and quartz.

OCCIDENTAL CON.—Continue to extract ore of fair quality from the stopes on the 400 and 450 levels. The crosscut from the bottom of the winze below the 550 level is in twelve feet, showing low-grade quartz. East crosscut No. 2 is in 242 feet, the face in hard porphyry. The 650 level main north drift is extended 171 feet, showing low-grade quartz. Crosscut No. 2 from the end of the drift is in 24 feet and has reached the clay wall. The formation passed through was low-grade quartz and bunches of good ore.

Eureka District.

DIAMONDVILLE. — Eureka *Sentinel*, July 19: The Diamond mine is reported to be looking away up. The new boarding-house is the handsomest and most substantial structure of the kind in this district. A large gang of mechanics and laborers are busily engaged in the erection of the new machinery below the mouth of the new tunnel, which is now in about 300 feet. Diamondville presents a very solid and businesslike appearance, and will, no doubt, be to Eureka in the future what Ruby Hill was in the past.

ORE SHIPMENTS.—During the present week the

Eureka & Palisade railroad shipped 490 tons of ore to the Salt Lake City smelting works.

Tuscarora District.

NEVADA QUEEN.—*Times-Review*, July 18: Upraise from 600 level of North Belle Isle is up 59 feet. Rock is hard, breaking bad. Progress for the week, 13 feet.

NAVAJO.—West crosscut at the north end line, 250-foot level, extended 16 feet.

DEL MONTE.—2d level: Line crosscut east has been advanced 9 feet and west 17 feet. Going east should intersect upraise from 3d level in about 10 feet.

YOUNG AMERICA SOUTH.—1st level: West drift extended 12 feet, and cut a ledge running northerly and southerly, and carrying one foot of good ore.

BELLE ISLE.—Upraise from south drift, 350 foot level, extended 11 feet, rock hard and air bad.

GRAND PRIZE.—400-foot-level: Stopes on the east and west vein continue to yield a good quantity and quality of concentrating ore. Stopes from the south drift are furnishing the usual quantity of $20 concentrating ore. Concentrator running steadily and doing good work.

COMMONWEALTH.—The work of extracting ore has been resumed preparatory to starting the mill, and work in some of the drifts on 3d level has been suspended for a few days, owing to scarcity of miners. Two hundred and twenty-five tons of ore hoisted; average assay, $27.21 per ton. The mill is being put in order for starting.

NORTH BELLE ISLE.—No. 2 upraise from north gangway, 600-foot level, extended 6 feet, vein showing bunches of good ore. West crosscut from north gangway, same level, extended 14 feet; face in vein formation.

NORTH COMMONWEALTH.—3d level: No. 1 raise from No. 1 south drift has been connected with 2d level, giving fine ventilation. Ore chutes are being put in, ready for stoping. The ore bin being built on the surface will be completed this present week. All ore hoisted heretofore has been dumped on the ground.

ARIZONA.

FORTUNA. — Prescott *Journal-Miner*, June 17: J. R. Duling has taken a working bond, with privilege of purchase, of the Fortuna mine on Lynx creek, Walker district, and put a force of men at work to-day, developing the property. The general impression seems to be that Mr. Duling has an excellent property.

SILVER KING.—The shaft in the Silver King mine is down 130 feet, at which point they are cutting out a station for the purpose of drifting. Some of the richest ore yet discovered in the mine was struck at this point, being gold sulphurets, running several hundred dollars per ton.

ORE RECEIPTS.—W. M. Claypool reports heavy receipts of ore at the sampling works, indicating great activity among miners. The ore is arriving from nearly every district in the county.

COPPER. — Both water-jacket furnaces of the United Verde Copper Co. at Jerome are running. A new reverbatory furnace is also being constructed.

HASSAYAMPA.—W. H. Harlan was in town today, and says that his mill on the Hassayampa is still crushing ore from the Howard and other mines owned by him there. The Aztec, in which old workings have been found, and in which relics of the stone age have also been discovered, continues to look well and yields good ore. About 40 men are at present employed in the Ryland mine. Mr. Riley expects to start the mill up again next Monday. The latter has been closed for some time, being remodeled.

TIP TOP. — Prescott *Journal Miner*, July 17: Messrs. Bircben, Bowers and Herman are doing much work on several claims around Tip Top, and are shipping every few weeks a carload of carbonate to Socorro or El Paso. The Tip Top, under its new management, is turning out a large quantity of pay ore. Several lots shipped from this property have run out $1000 to the ton. Marlow, Carter & Johnson, on the Bullwhacker claim, are striking it rich. They have a shaft 75 feet in depth, with several drifts all in good rock. The vein is about three feet in width, a high-grade streak four inches wide running through the center of it. The ore is free milling, without any base admixture.

SILVER MUSEUM.—The well-known Silver Museum mine, a few miles beyond Gillette, has lately been leased by South, Lenhart & Co. of Trinidad, Col., who are shipping rich ore and developing the mine by running drifts into even richer rock.

FOURTH OF JULY.—The Fourth of July mine, owned by Tom Wade and Louis Johnson, is being profitably worked. This property is located on a steep side-bill, and a tunnel has been run along the ledge to the depth of 400 feet. Another tunnel has just been commenced, which will strike the ore body 100 feet farther down. The ore is very rich, but is charged with sulphurets, arsenic and antimony.

PAY ROCK.—J. W. Taylor and H. Norton are shipping pay rock from the Seventy-Six mine, and small lots are brought to Phoenix frequently by chloriders who seek simply for a grub stake to purchase powder, tools and provisions, and who are earnestly working to turn their prospects into mines.

COLORADO.

TELLURIUM GULCH STRIKE.—Aspen *Times*, July 17: C. A. Goss and F. F. Nelson are feeling somewhat elated over the showing made in the New York mine in the Lincoln district, which they are working under lease. The property has always produced some good ore, but the lessees have come upon a chute of good size that promises to yield them a handsome profit. The ore produced from the new discovery runs 114 ounces and its character is very desirable.

THE HANNIBAL.—The Hannibal is now showing a streak of ore that runs up to 140 ounces, while there is a considerable body of mineral averaging from 40 to 50 ounces. The rich streak is about 16 inches thick.

DAKOTA.

D. & D. SMELTER.—Deadwood *Pioneer*, July 15: The D. & D. Smelter went out of blast yesterday morning on account of being entirely out of pyritic ore. A carload of coke was received at the works on Sunday, and four more are on the way here. The smelter will blow in again as soon as a supply of pyrites can be hauled. Everything about the plant is working to perfection. The Hester A. Co. began delivering ore yesterday at the Deadwood and Delaware smelter. The delivery of Seabury-Calkins and Maggie continues without interruption. The Northwestern began the delivery of coke at one o'clock Monday morning and continued it all day yesterday.

IDAHO.

HUNTER DISTRICT.—Wardner *News*, July 12: Under the management of Francis Agnew the Hunter mine keeps 75 men employed with John Hanley as superintendent. The Burleigh drills are doing good work in tunnel No. 3, known as the Kavanaugh tunnel, where a fine body of ore is visible. The mill, under the direction of Robert Herman, late of Wardner, is running day and night treating over 100 tons of ore every 24 hours.

LUCKY FRIDAY.—This mine is now under the management of Robt. T. Horn, who has the property under bond and lease for six months. Four men are continually employed. The incline is down 80 feet with a crosscut of 40 feet in fine ore—chlorides and carbonates. The ore is free milling and will run 100 ounces to the ton.

CENTRAL.—Jack Empfield keeps steadily developing the Central mine on Boulder creek, which is daily improving in appearance. A New York syndicate having an option on the property for 30 days are expected here immediately.

DAISY.—John Lanihan, P. McGraw and Dan Finn are still sinking on the Daisy. Last week they struck a fine body of ore near the creek.

SUMMIT DISTRICT.—J. W. Sweeny is the discoverer and locator of what is known as the monumental group of claims lying between Cougar and Wesp gulches in Summit district. The ledge is well defined, running east and west with hanging and foot walls of decomposed slate. The ore is carbonate of lead, containing about 50 per cent lead and carrying considerable silver. The property is owned by J. W. Sweeny, A. E. Mayhew, and S. P. Donnelly.

A STRIKE.—Idaho *Avalanche*, July 19: Geo. W. Stoddard, who is about as persistent a prospector and good judge of ore as any in the camp, has for some time past been working on one of his claims, the Injector, situated near the Morning Star and from which some exceedingly rich ore has been taken in the past, and has recently struck a body that far exceeds in richness anything before found. Much of the ore is literally full of gold and silver and will go way up in the thousands per ton.

LOWER CALIFORNIA.

ALAMO.—*Lower Californian*, July 17: A run of 13 tons of Aurora ore through Kerr's mill the other day netted 40 oz. of gold. The ore was from that part of the mine leased by Vermason and partners. Shaw and partner, placering in the little gulch above the Princesa, struck it rich the other day, washing out two ounces in one day and finding rich float indicating a blind ledge. They are prospecting for it. The Princesa Co.'s big boilers, pumps, roller mill, feeders, crushers, etc., arrived Saturday, and the boilers are being placed by Supt. Rodda on the Indio and Ulises, the two great mines (supposed) of the camp. These mines have been water-logged for a long time but the ore taken out previous to their overflow was of great richness. Since then, also, many tributers have worked stringers on the Ulises, and came as near to getting rich as is possible under the contract system in vogue. A foundation is being made for the duplicate Huntington mill for the company, near the present one. Extensive banking is being done and large excavations made at the mill site. About twice the present number of men employed by the Princesa Co. will be required from now on, besides a large force of tributers who are waiting until the water can be pumped out of the San David, Indio, Ulises and others. The Telémaco has been hard at work under Foreman Poole and almost enough ore is extracted to supply the mill. The El Paso mill is working on custom ore and has all the work it can do. Supt. McLaran is quite popular with the boys. L. B. Howard has put a force at work on the Arabella, and the rest of the Butler mines will be opened soon. Kerr's mill is kept busily at work and good results are obtained. Col. Lane's old reliable Wiswell mill grinds away on a stack of ore that is never suffered to diminish. Good satisfaction exists among all who have made runs through this mill.

THE CEDROS ISLAND MINES.—The steamer Pacheco came up from Cedros Island, Tuesday forenoon, with a few passengers and 2549 sacks of gold ore. Over 1000 sacks of ore had to be left at the landing, owing to the lack of room on the steamer. Wilson, a teamster in the employ of the mining company, discovered two ledges of silver ore near the steamer landing a few days ago, one of them assaying 78 per cent silver. They will soon be developed. A ledge of iron ore, carrying gold and silver, is also among the new finds on the island.

MONTANA.

BRUCKNER FURNACES.—Helena *Review*, July 17: Fraser & Chalmers have ordered 106 Bruckner furnaces for the Anaconda Co.'s upper works. When they are put in that company will have 200 in operation.

PLACERS.—The placer mines of Diamond, Jefferson county are actively at work and not an idle man is found in the camp. Last Monday the Diamond express brought down W. J. King, who had between $8000 and $10,000 worth of gold dust with him. The trip was made at night. If the water continues even as it is now, the yield will be considerable this summer.

CASTLE.—Mr. Suydam, of Castle, was here Monday on his way to Butte. He is of the opinion that Castle is the greatest carbonate camp in the world. He thinks the Yellowstone is as good a mine as the Cumberland.

STONY CREEK PLACERS. — Phillipsburg *Mail*, July 19: Jesse Wilkinson, foreman of the Stony Creek placer property, left Phillipsburg Wednesday morning at 4 o'clock with a wagon-load of supplies and a crew of men to commence operations on the ground. They will get the ditch in shape and get down to work in about 20 days, the *Mail* is informed. There is considerable preparation to be made before development work can be properly carried on though it is believed that everything can be gotten in running order in that time. Mr. Wilkinson is an experienced miner and will get whatever value there is in the placers. There is plenty of water and ground, and as the latter prospects well, we see no reason why the property should not pay from the time the water is turned on.

COMBINATION.—Sinking has been commenced on the new shaft again, and will doubtless be continued for 50 or 60 feet. They are now down over 130 feet. When the necessary depth has been attained they will run a drift and stope the ore out. The buildings of the company are being given a coat of paint, and everything is going on satisfactorily. A few men have been put to work on the Tim-Smith claim, which the company bonded some time ago, and upon which it is understood that they have recently raised the bond. They also contemplate doing some work on another one of their undeveloped properties.

THE HIAWATHA.—Anaconda *Review*, July 19: The Hiawatha is certainly promising to be a great mine. The lead has a width of 11 feet. Through it for some time have been hair-wide streaks of pure silver, and these seem to have been converging to a common point, until now the streak of rich ore running from 5000 to 20,000 ounces to the ton is about an inch wide, and what is best news, is that it is increasing in width. The tunnel of the Hiawatha is in 320 feet, and from the end there is a winze sunk 57 feet, making a depth on the vein of 160 feet. Work is progressing on the shaft, a steam hoist is on the way to the mine, and about the middle of this month the men will begin sinking the shaft and the work prosecuted as rapidly as possible. Eleven men are employed.

NEW MEXICO.

CONCENTRATES.—Silver City *Enterprise*, July 18: Messrs. Bell and Brown shipped a carload of concentrates from the Tampico mine, Pinos Altos district, during the week. Three tons of concentrates from the Good Hope, Chloride Flat, Carson & Lucas owners, was among the ore shipments of the week ending July 19, 1890. The probabilities for the immediate resumption of work on the Solid Silver Co.'s claims at Black Hawk are very encouraging. The one-sixth interest in the Cora Miller, owned by John T. Mitchell, has been sold to Maj. W. A. Hutchinson of San Angelo, Texas. The mine is now entirely owned by San Angelo and Los Angeles people. A new strike which is looking well at grass-roots was made by Dan Casey in the Lone Mountain region last week. The negotiations, for some time pending in reference to the sale of the Maud S. in the Mogollons have been consummated, papers being placed in escrow a few days since.

BALD MOUNTAIN.—Mining matters are picking up, and prospecting at Bald Mountain is becoming quite active. John Stone is taking out high-grade smelting ore from the Carrita, which is looking well, and bids fair to yield the energetic miner excellent returns for his labor. A carload of copper ingots, 15 tons, will be ready for shipment from the Anson S. mine by next Tuesday.

HACHITA.—The developments now being made by Mr. Tyler on the mine he recently purchased have shown wonderful improvement. The product is valuable shipping ore. The lower grades will be milled in the vicinity of the mine.

OREGON.

A CLEAN UP.—Grant's Pass *Courier*, July 16: Mr. H. B. Whiting has cleaned up in his mine near Kerbyville, and intends this fall to bring in a ditch from Sucker creek so he can work his claim the entire year. Nick Thos and James Farren are engaged in mining on Silver creek above the falls. They will endeavor to break the falls so they can mine the ground above which is known to be very rich, but not having sufficient fall has not been worked. Frank Dessenger, while in the city this week, kindly showed us a nugget taken from the hydraulic mine owned by John S. Haverly on Canyon creek, which weighed $20.10. Messrs. Frank Norris, John F. Ryan and E. Baldwin were in the city from their Reuben creek mines Saturday, reporting the diggings to be paying well, and that they had taken out 24 ounces in two weeks and three days, numerous nuggets weighing from $1 to $30, and that their claims were paying $10 per day to the man.

PROSPECTING. — Jacksonville *Times*, July 19: The Illinois river district will be thoroughly prospected this summer. A clean-up was made at John Goff's hydraulic mine near Leland recently, with the best of results. Lance & Duffield have done well at their mines in Foot's creek district, cleaning up over $3000 this season. One of the best clean-ups in southern Oregon was made at the placer mines of Hosmer & Anderson in Foot's creek district. It is stated that they took out $5000 in gold-dust. Norris, Ryan & Baldwin report having taken out 24 ounces of dust in 16 days recently, including nuggets ranging from $1 up to $30, from the Reuben creek mines. The ground above the falls in Silver creek will be worked by Nick Thos and James Ferren this season. They will have to break the falls in order to reach the richer diggings. A local exchange says that the Brookfield & Griffiths quartz ledge near Tolo will be worked by a company, and a 10-stamp mill erected this summer. Eight men are now at work in the mine.

UTAH.

LITTLE COTTONWOOD. — Salt Lake *Stock Exchange Journal*, July 17: Little Cottonwood has been heard from again in the shape of a reported find in the Emma mine, that is said to be immensely rich. The Emma is largely controlled by an English syndicate, but a number of Salt Lake people are interested in the property. The Emma has been a great producer and dividend payer, but has been in litigation for some time.

CINNABAR AND GOLD.—J. F. Corker has on exhibition at his office a fine specimen of cinnabar and gold ore. The ore goes from $10 to $20 in gold and a large per cent in cinnabar. The ore comes from a new find in Utah in a new district. Mr. Corker and several Salt Lake parties have a bond on the claim. This ore vein is 20 feet wide and is inexhaustible.

ACTIVE.—Eureka *Chief*, July 19.—There is increased activity in the south end of the district. Several new discoveries of rich ore have been made in the past few months, and the prospectors, encouraged thereby, "are getting down to their knittin'." Several promising prospects have been bonded by outside capitalists who are putting in machinery and preparing to go after the pay-dirt in the most approved fashion. Mining men are arriving at Silver City daily on the lookout for "something good," and all in all there is every indication that our sister camps are entering upon an era of unprecedented prosperity.

ANOTHER BIG SALE.—Monday morning Wm. Matthews, Dennis Sullivan-Beck and Frank McHatton sold to the Continental-Eureka Co. their three-fourths interest in the Lookout and Summit mining claims, situated above the Blue Rock on Eureka Hill, and adjoining the Alta and Overman. The purchase price was $80,000 and it was spot cash. These are the claims which the owners and the Centennial-Eureka have been lawing over for some time. Thus does Tintic District continue to wax great.

THE EMMA STRIKE.—Salt Lake *Tribune*, July 19: A report gained some currency a day or two ago that a strike had been made in the Emma mine at Alta. As is often the case, this rumor assumed various forms, while nothing definite could be learned except by a visit to the property. Yesterday a *Tribune* reporter went to Alta and learned through various sources the real facts. Going back to the history of the Emma mine it is enough to say that in 1871 it was sold for $1,200,000, and it has produced in all about $5,000,000. Since 1876 the mine has not paid anything to the owners. The early workings extended down about 250 feet below the collar of the shaft. After working out the ore chambers in that portion of the mine, down to that depth, the company began another system of developing and working the property through the Bay City tunnel. This tunnel was run nearly 300 feet below the collar of the old shaft. This tunnel is now in 1800 feet. Below the level of this tunnel a shaft was run some 400 or 500 feet and levels run to the lode. Prospecting is still going on at six different points in the mine and ore has been found at all these places. Below the Bay City tunnel level ore is found, but is of very low grade. It is above the Bay City tunnel level where the late developments of ore have been made. The best strike is 200 feet higher than the tunnel, and what is important, is in entirely new ground. The old chamber, from which millions of ore was taken, fell in after it had been dug out. Lately a drift was run through this old chamber into the hill a distance of 200 feet. In doing this the top of an ore chimney was cut through, showing a vein two feet wide. It was then decided to sink an incline shaft on this vein, which has a dip of about 45 degrees. This shaft has gone down 25 feet, and in that distance has widened from two feet to eight feet and it is still widening. This vein at the bottom of the shaft has five or six feet of good ore out of the eight feet in width, while the balance is good for concentrating. This ore is all taken out each day in sinking this shaft, and about 60 tons have already come out. The value of this ore, taken clear across the vein, is about 50 ounces silver and about 40 per cent lead. This ore was cut about two weeks ago, and it has been growing better every day. This strike alone places the mine in a more hopeful condition than at any time in the past 10 or 12 years. Besides this strike, there is enough in other places where development work is being pushed to give hope for the future. The mine is now where it pays its way, and the big strike promises to open out into a great bonanza, and if so, there is in store a bright day for Little Cottonwood. The present outlook is certainly favorable for a big mine again of the Emma.

MINING OUTLOOK. — *Inter-Mountain Mining Review*, July 17: The mining outlook for Utah is beginning to shine with a new and delightful light. All along the line from Cache county in the north, to the Dixie land of the south, come words of greeting and great joy. New discoveries are being made every day, we might say every hour, and old claims are being delved into and made to produce in a manner which a year ago was neither thought nor dreamed of. The truth is, that mere speculation in mines is rapidly giving way to actual labor and substantial development, and those who hold properties of any consequence, realizing that the day for talking mines into prominence has long since passed, if for no other reason, are bestirring themselves in a manner at once praiseworthy and profitable.

PARK SHIPMENTS.—Park *Record*, July 18: The Ontario bullion product for the week was 35 bars, containing 19,169.60 fine ounces of silver. This week 9n22.5 pounds of high-grade and 8257 pounds of Daly base sulphides from the Russell lixiviation process were shipped from the Marsac mill. The shipment will aggregate a considerable sum in value. During the week there were shipped from the Crescent concentrator 270,970 pounds of Crescent concentrates, 161,7n0 pounds of Gilsch & Campbell's Crescent lease concentrates and 46,000 pounds of Hatch, Prisk & Co.'s Creole lease concentrates; total, 478,670 pounds. For the week just ended, the Mackintosh sampler received and forwarded 592,030 pounds of Ontario ore, 131,800 of Daly, 7n,890 of May Flower No. 7 leaser's ore, 119,150 of Flindt & Varcoe's May Flower jiggings, and 186,790 pounds of Anchor concentrates from the Union concentrator; total, 1,100,660 pounds.

WASHINGTON.

MACHINERY FOR THE LONE STAR.—Okanogan *Outlook*, July 17: As stated in the *Outlook* last week, the Lone Star will remain idle but a short time. General Manager Henry Lawrence, who left for Tacoma immediately after the fire to consult with his partner, Allan C. Masnn, has sent in word that new machinery has been purchased and is now in transit from Butte, Montana. Several additional men have been put to work clearing off the ground for the new buildings, which will be considerably larger than the old ones.

PROSPECTS OF MINES. — Goldendale *Courier*, July 19: Messrs. Haggard & Stout, who went out to Mt. Adams some time since, sent in some specimens of quartz croppings, which show considerable iron and some gold, and strong indications of lead and silver. We are informed that a mining district was organized with Almon Baker as recorder. It is beyond a doubt that if these men should succeed in finding a well-defined ledge of such rock as was sent us, that it is only a matter of a few months until there will be some rich strikes made. It is a foregone conclusion, in our estimation, that good-paying mines can be found nearer to this city than Mt. Adams.

MECHANICAL PROGRESS.

Philosophy of the Injector.

There is something mysterious to most engineers about the action of an injector. It seems a sort of paradox that steam of low pressnre can force water into a boiler against a higher pressure, yet we all know it is a fact. The action of the injector, too, is very hard to explain simply, although it may be simple enough itself. We notice a monthly contemporary undertook the task to explain its action, on the basis that it is the momentum of the moving steam that gives the injector its peculiar power. This was explained on the principle that a bullet thrown from the hand was harmless, yet the same mass thrown from a rifle has in its increased velocity greater momentum and greater penetrating power. Momentum has a great deal to do with the action of the injector, but there are other factors necessary. In explaining the injector we should not omit to mention that this momentum is concentrated on a very small spot, hence the energy that is generated at this point is of vast importance in the problem. If it were not for this difference in area of jets, or concentration of the energy in the moving steam, the injector would be of little value, depending on momentum alone. The steam condenses, and the energy that in the momentum of the steam affected a large area is condensed so that the same momentum affects a smaller area, hence is able to do considerable work. Practically the same thing is seen in the use of a burning-glass, by which the heat is condensed and brought to bear on a certain spot. There is no more heat in the matter. The same amount of heat passes through a piece of glass of an area equal to that of the lens, but in one the heat is condensed into one spot, and in the other covers a considerable area. So in the injector, there may be just as much momentum in an open pipe or one with a jet, but the one with the jet will force the water because all this momentum is concentrated on a smaller area, just as the heat in the burning glass is. A correspondent who has been making a test of his boiler has come across this point, over which he has pondered without reaching any definite conclusion. Water is forced into the boiler through an injector, and the question is this, whether the steam that is condensed in the injector is not carried back to the boiler and so re-evaporated without being weighed, the boiler thus actually evaporating more water than is credited to it. "This steam," he says, "must have been evaporated once, when used in the injector is condensed and goes back into the boiler as water, and must be evaporated over again just the same as though water from the tank direct. It has occurred to me that all this might be offset by the heat it gives to the steam, but as I figure, the evaporation from the temperature, after it has passed the injector, it seems as though this is offset. How am I to settle the matter?" We should pay no attention to the injector, but figure the evaporative duty of the boiler from the pounds of water pumped into the boiler. It will be found that the heat that has gone into steam in the boiler once is to all practical purposes still there, although the heat does travel from the boiler through a pipe and injector back again to the boiler. The heat will still be in the boiler, and if there must do its part toward evaporating more water, or one might say, the heat is there with which the steam condensed can re-evaporate itself after returning to the boiler.—*Boston Journal of Commerce.*

IMPROVEMENT IN SOFT-BACK STEEL.—Announcement is made that M. A. Howell, Jr., London, has taken out a patent for improvements in the manufacture of soft back steel. The invention relates to the manufacture of plates or flat bars of steel having one side highly carbonized and the opposite side practically free from carbon. Such steel is said to be less liable to break or crack while hardening, and is more tenacious when in use where great rotary force or heavy blows or strains are required. Plates or flat bars of soft steel or fine iron in pairs of equal size are placed back to back with a film of clay or other refractory material inlaid between them. They are then clamped or wired together, and the several pairs are placed "in a receptacle or flask stratified between layers of granulated charcoal." The flask, furnished at one end with an inlet tube and cock and at the other end with an outlet cock, is placed horizontally in a muffle. When the heat of the furnace has raised the temperature of the flask to a low red heat, a current of hydrocarbon vapor is driven over the plates, and when the heat reaches the cherry-red stage, the flow of gas is diminished and the operation continued until the metal has taken up enough carbon. Finally the cocks are closed, and the flask is disconnected and allowed to cool in an atmosphere of hydrocarbon. When cool, the receptacle is opened and the plates are taken out and forged, hardened and tempered in the usual way.

RATTLING OF MACHINERY.—The Pittsburg *Dispatch* tells of a ten-horse power engine which, on the upper story of a silverware manufactory, created such a commotion as to rattle the silverware on the shelves a hundred feet distant. A change of 25 revolutions in the speed, which change was in the direction of increasing the speed, entirely stopped the vibrations. The question is often asked: "Why do some gears rattle and others not on machines that are built just alike?" This is no doubt owing to the smoothness of action in the gears. The teeth should come in contact gradually and not meet with their highest driving strain until they reach the line of centers and then part with the same easy motion. The least jar, knock or pound from the slightest movement is going to make itself known.

"DETERMINING THE HAMMER BLOW."—A bill has been introduced in Congress at the instigation of the Franklin Institute and the U. S. Mechanics' Association, asking for an appropriation of $25,000 to defray the expense of determining the exact measurement of the "hammer blow" as it is produced by the counter-balance of a locomotive driving wheel. The *Railway Review*, in noticing the fact, has this to say: We should be as much pleased as any one to see this much discussed question settled, but we fail to understand why Congress should be asked for an appropriation to settle this question any more than in the case of other and more important ones involved in locomotive construction. Any road can determine in very short order the practical limits within which the weight of counter-balances must be kept if bridges and track are not to suffer. To determine the exact measure of the so-called hammer blow in foot-pounds is not so easy, nor is a knowledge of it especially needed at present except for the same use as that to which the appendix of an arithmetic is put—to give the correct answers to the mathematical problems contained in it. This would be an immense relief to the mathematician, and Congress might have sufficient compassion to pass the bill; but, while it adds to knowledge of the master mechanic, it would still leave him to find out how much of this kind of a blow his bridge would stand, and how little counter-balance he could use and still neutralize the effect of the reciprocating parts sufficiently for all practical purposes. If the assistance of Congress is really required, it would be better to have the best practical relation which the weight of the counter-balance and the reciprocating parts should sustain to each other so fully demonstrated as to remove all doubt from the minds of master mechanics. If Congress is going to hear the expense of scientific investigations desired by private interests, we think the list of applicants for such favors will increase very rapidly.

GOODS FROM DIES BY HYDRAULIC PRESSURE. Machinery for cutting out iron work by dies and hydraulic pressure is among the most important devices for labor-saving. Commencing in a very small way many years ago, such machinery is now constructed and employed on a mammoth scale. Only a few years ago, cooking utensils of small caliber began to make their appearance and excited much comment. Quite recently the public was not a little surprised at the successful establishment of works for cutting out a boat and shaping it at one operation from a single piece of iron; and now we notice a new departure in the same direction in wagon-building at Leeds Forge, England, where machinery, presses and appliances are being put down with a view to manufacturing railway wagon bodies from one piece of metal—iron or steel. The wagons are to be made by means of a press and dies, and in a comparatively short time from a heated plate the sides and bottom of a wagon can be formed. There will be no need of angle iron or steel, or of riveting.

A CHIMNEY THAT WILL DRAW.—To build a chimney that will draw forever and not fill up with soot, you must build it large enough, 16 inches square. Use good brick and clay instead of lime up to the comb; plaster it inside with clay mixed with salt; for chimney tops use the very best of brick, wet them and lay them in cement mortar. The chimney should not be built tight to beams and rafters. There is where the cracks in your chimneys come, and where most of the fires originate, as the chimney sometimes gets red-hot. A chimney built from the cellar up is better and less dangerous than one hung on the wall. Do not get your stove-pipe hole too close to the ceiling, but about 10 inches from it.

STEAM THERMOMETERS.—Thermometers for use in the boiler room for testing purposes, says the Boston *Journal of Commerce*, should be accurate, or their variations known. This can be readily proved by inserting in an open pot of boiling water, when the thermometer should register 212 degrees on the sea level and one degree less for each 500 feet above the level of the sea. Some steam thermometers are specially made with a stuffing-box arrangement, so that the bare thermometer is exposed to the current, but we prefer the oil-cup device because the thermometer can be removed or inserted without shutting down, and the results are just as accurate.

STEEL WIRE has been wrought into the form of a belt to run on pulleys by a process that will allow it to conform readily with the curve of the smaller wheels. The latest device seems to be an imitation of the leather-link method, which must give joints enough to work loose and to make all the slack that could be asked for.

A BUTTON sewing-on machine has been invented in England, and is said to work to a charm.

SCIENTIFIC PROGRESS.

Magnetization of Steel Cylinders.

An interesting note concerning the effect produced upon cylinders of steel along which strong currents are passed is given in a recent issue of the London *Electrician*. It is said that in 1887 M. Paul Janet showed that cylinders of steel, along which strong currents had been passed, became permanently magnetized transversely. By extending the experiments some very striking results have been recently obtained which are thus described:

The cylinders used were split longitudinally, and, after the passage of the current, the magnetism of the parts was tested by iron filing figures. It was then evident that not only was the iron magnetized transversely, but the intensity of the magnetization varied in a regular undulatory manner along the bar, the lines of force arranging themselves in somewhat the same way as fine powder in a vibrating tube. The effects could not be accounted for by supposing the iron heterogeneous, because the nodes and loops occurred at about the same distance for different bars of various diameters and lengths. M. Decharme concludes that there is a great difference in the magnetization of an iron core by a steady current passed through a solenoid surrounding it, and that of an iron bar through which a current actually passes. In the latter case, M. Decharme considers that the current is propagated in waves during the very short time necessary to produce the magnetization, and compares the phenomenon with the well-known undulatory magnetism produced by the oscillatory discharge of a Leyden jar. The effect is probably due to the starting of the current, and it is therefore unfortunate that no particulars are given of the manner in which this was done—whether switched on suddenly or increased very gradually to its full value. In the latter case, no effect might have been produced, as strong currents were needed to show the phenomenon. The experiments of Blaserna have shown that undulations do actually occur for the first few moments after starting the current, and it is possible that these may be much accentuated when part of the conducting conduit is of iron. The experiments are of interest because they suggest that many phenomena usually attributed to want of homogeneoneness in iron may really be due to successfully starting and stopping a magnetizing current.

Meteorological Notes.

The explanation of the peculiar density of thunder clouds is said to lie in the fact that the vapor is partially condensed into drops by the electrical action. This is emphasized by the fact of the larger drops and more abundant fall of water immediately after a lightning flash. During a thunder-storm which recently raged in Berks county, Pa., a number of people were stunned, and the air seemed to be charged with electricity to an extent never before known. At several places balls of fire entered private dwellings exploding with fearful sounds.

The amount of water which the sun raises from the earth is estimated at the enormous weight of 37,000,000,000 tons a minute; the quantity of coal required to produce a heat in any way equivalent to the sun's is calculated to be 12,000,000,000,000,000 tons.

French weather predictions last year reached the highest recorded accuracy, 90 per cent proving correct.

When a storm is advancing the wind blows to meet it. Thus a wind blowing from the east or southeast indicates the approach of a storm from the west. When the storm center has passed, however, the wind changes and follows the storm.

A NEW FUEL.—Another cheap and simple fuel discovery is announced in Germany, which possesses advantages that will tend to bring it into universal use. The process which has been patented at Munich, Bavaria, converts turf into a firm and highly valuable combustible material resembling anthracite coal, and burning without smoke or odor. Through a successful combination of several oft-tried processes, the cost of production has been brought down to a point that will admit of a patent turf entering into competition with coal.

PHOSPHORESCENT INFECTION.—The curious discovery has been made that the phosphorescence frequently exhibited by the crustacea is infectious. A French naturalist, M. Giard, lately traced the phosphorescent light in *Talitrus* and other crustacea to bacteria in the muscles, which showed signs of disease. On inoculating healthy individuals, the same luminous appearance was produced. The disease runs a regular course, and the crustacea died in three or four days, the phosphorescence lasting a little after death.

THE ARTIFICIAL PRODUCTION OF RAIN.—An interesting experiment is likely to be soon made by the Agricultural Department on one of the arid regions of the West, the result of an appropriation of $2000 in the Agricultural Appropriation bill, for the purpose of experimenting on the production of rainfall by the explosion of dynamite. Senator Farwell advocated the appropriation, as he believes the project is a feasible one. The plan is to send up 25 pounds of dynamite on inexpensive balloons, the charge to be exploded by time fuses. Both the Senator and Secretary Rusk are credited with the conviction that a succession of these explosions will produce rain. The proposition recalls the efforts of a well-known resident of San Francisco, who, some years ago in Tulare county, essayed to enlist the co-operation of a number of ranchers in trying to produce much needed rain by similar means. His suggestion created a good deal of amusement, and he was subjected to considerable badinage. Military men, however, have frequently remarked that a severe cannonade was followed by rain. The result of the experiment will be watched with interest.

BOILING OF WATER NOT A GUARANTEE OF PURITY.—We are accustomed to be told that the most impure water will be rendered pure by boiling, and that in this we have an absolute safeguard against the danger of water containing disease germs. Now, while it is true that boiling will kill the germs of disease, yet the fact has been brought to our notice, says *Annals of Hygiene*, by so high an authority as Dr. Chas. M. Cresson, that while boiling kills the germs of a particular disease, it yet, in reality, renders the water more impure than it was before, because, by the very death of these germs, dead organic matter is allowed to remain in the water, which is polluted by putrefaction. Hence, while boiling is a most excellent precaution against the occurrence of typhoid fever or similar diseases, when we have occasion to think that the germs of these diseases exist in the water that we drink, yet we must remember that this boiling does not purify the water; it simply removes from it the specific power to produce a specific disease.

IMPONDERABLE ELEMENTS.—We were astonished, says the Newburyport *Herald*, to find that one of the most recent school-books keeps up the old ideas that heat, light and electricity are "imponderable elements;" that is, absolute matter that does not weigh anything. All modern science says that these so-called elements are not matter at all, but that they are simply different kinds of vibrations in matter. It is easy to understand that what we call sound is simply a vibration of particles of matter that address themselves to our ears; that light is another kind of vibration to which the nerves of sensation respond, while electricity is still another form of vibration, or, as it is considered by some scientists, not a different, but a more rapid form of vibration. Just as a friend may take you by the hand and shake you all to pieces, just so electricity shakes and destroys whatever it takes hold of, disintegrating and virtually annihilating the ultimate particles.

RAPIDITY OF THOUGHT.—Prof. Donders of Utrecht recently made some interesting experiments in regard to the rapidity of thought. By means of two instruments which he calls the necmatachograph and the ncernatachometer, he promises some important and interesting results. His experiments up to date show that it takes the brain one .067 of a second to elaborate a single idea. Writing in regard to this, Donder says: "Doubtless the time required for the brain to act is not the same in all individuals. I believe, however, that these instruments may be perfected until we will be able to determine the mental caliber of our friends without our friends knowing that we are testing their aptness." The professor says: "For an eye to receive an impression requires .077 of a second, and for the ear to appreciate a sound .149 of a second is all that is necessary which, however, shows that it acts with nearly double the rapidity of the ear."

ZINC DETERIORATED BY BRICKWORK.—The fact is mentioned in a German newspaper that, under some conditions, sheet zinc, when in direct contact with brickwork, suffers to an appreciable extent from rapid corrosion. It appears from this account that, in building the Berlin city market halls, a portion of the zinc work which rested upon brick walls was found to be deeply pitted in a number of places, this being particularly the case where the metal was close to the bricks. Chemical examination of these results in showing that they contained as high as 1.14 per cent of soluble salts, capable of producing the destructive effects in question, and stimulated to more energetic action by moisture. The proportion of such salts of course varies with different kinds of bricks, while in some there may be nothing to induce any such corrosion. As a preventive, roofing felt or similar material may be placed between the zinc and brickwork.

STRUCTURE OF FLAME.—Prof Dewar, in his lecture, at the Royal Institution, on "Combustion and Flame," produced a "picture" of a flame made by itself, in which its structure was revealed. This was effected by two hook-covers of moistened asbestos. These were suddenly clapped together on the flame, and the result was a picture of the flame in different copper tints.

MINUTENESS IN ASTRONOMICAL WORK.—When Sir John Herschel was defending the character of astronomical science, in view of an error of nearly 4,000,000 miles in estimating the sun's distance, the correction was shown to apply to an error of observation so small as to be equivalent to the apparent breadth of a human hair at a distance of 125 feet.

Good Health.

Health of the State.

The State Board of Health Report for June is at hand. The most 84 localities have made their returns which indicate an improved condition of health throughout the State. The Secretary of the Board, Dr. C. G. Tyrrell, says in his report that "until the official result of the late census is published we have to accept the estimated population as furnished by our own correspondents. The actual death rate is therefore uncertain until we can get the correct number of the population affected. There has been very little zymotic disease reported as particularly fatal, except cerebral fever and cholera infantum, and these in limited number."

Diphtheria and croup have been collectively reported as causing 35 deaths, which indicates a very much lessened prevalence of disease. Twenty-six were from diphtheria and nine from croup. Typhoid fever is mentioned in a limited number of reports, the cases being all sporadic. From this time onward we may look for an increase in this preventable disease, as it seems impossible to educate the public upon the necessity of keeping the premises free from accumulating and decomposing filth. The air they breathe, the food they eat and the water they drink, through becoming contaminated, are dangerous to health. Reports from 84 localities indicate an improved condition of the public health. Disorders of the bowels were prevailing to some extent and some few cases of cholera morbus were noticed; this disease was no doubt induced by eating unripe or unsound fruit or vegetables. Zymotic disease, such as measles, scarlet fever and diphtheria were not prevalent anywhere, and where present were in a mild form without a tendency to spread. Cancer claims 27 deaths, a little short of its usual quota.

The cholera is increasing in Spain and it is not improbable that a lack of sanitary care will permit it to spread throughout Spain and then reach America through the Mediterranean or Eastern ports. It is supposed to have originated from opening the graves of some of the victims of the disease of 1885, and is of so equally virulent type. As it has been proven that cholera cannot prevail where perfect cleanliness is observed, it would be a matter of simple prudence to prepare to defeat any attempted inroad of this disease into California by a general clean-up of cities, towns and villages. Once the disease appears, this measure would be too late. We cannot be sure that cholera will not come to America; we hope it will not, but with the means of prevention so easily applied we would be criminal to neglect the warning thus timely given.

Danger from Electrical Currents.—Medical authorities who have studied the dangers to human life from electrical currents are agreed that this danger has been overestimated, and that the number of fatalities is not as large as represented. A medical journal has combined that electrical currents produce three kinds of severe accidents—instantaneous death, or severe burns, or traumatic neurosis caused by the mental and physical shock. Usually, if the person receiving the shock is burned, he is not killed. Practically, if contact with the wires does not kill, a burn or a harmless shock is the only result. Paralysis of the nerves or nerve centers is very rare. During the last ten years there have been only about 100 deaths in the whole world caused by artificial electrical currents. Taking as a basis of comparison the capital invested, the number of serious injuries met with in the electrical field is not as large as that in other great industries. The number of people killed by asphyxiation from illuminating gas is largely in excess of the number who meet death by coming in contact with heavily charged electrical conductors.—*Electrical Review.*

Sudden Starts, Jerks, Etc., While Asleep.—F. W. C.—Sleep restores vigor and tone to the brain and nervous system, and while one is asleep the muscles and tissues become relaxed. The spasmodic movements are due to nervous reaction for the most part. It is sympathetic sensations for the most part that cause the jumps and jerks that awaken when the person is just falling into slumber. Often external causes, a noise, a touch, the pressure of the bedclothing will produce such effects through the sympathetic nerves. Generally people whose nerves are very active during the day experience these not always pleasant sensations. They receive impressions, consciously or unconsciously, that somehow may revive in the early stage of slumber, and the sleeper catches a glimpse of a dream, in which he seems to be falling or exposed to vague danger, and an instinctive impulse to save himself is expressed in the jump or jerk that arouses to full consciousness.—*Phrenological Journal.*

Nutritive Value of Foods.—Speaking roughly, a quart of oysters contains, on the average, about the same quantity of actual nutritive substance as a quart of milk or a pound of very lean beef, or 1½ pounds of fresh codfish or two-thirds of a pound of bread. But while the weight of actual nutriment in the different quantities of food material named is very nearly the same, the quality is widely different. That of the very lean meat or codfish consists mostly of what are called, in chemical language, proteine compounds or "flesh formers," the substances which make blood, muscle, tendon, bone, brain and other nitrogenous tissues. That of the bread contains but little of these, and consists chiefly of starch, with a little fat and other compounds, which serve the body as fuel and supply it with heat and muscular power. The nutritive substance of oysters contains considerable of both the flesh-forming and more especially heat and force-giving ingredients. Oysters come nearer to milk than almost any other common food. Their values for supplying the body with material to build up its parts, repair its wastes, and furnish it with heat and energy, would be pretty nearly the same.—*Century.*

Bacilli in Celery.—Dr. Charles M. Cresson of Philadelphia states that he has more than once found the typhoid bacilli in the juice that he has squeezed out of celery grown near Philadelphia.

Shop Notes.

Wasting Power.—A prominent machine company, says a contemporary, having extensive business transactions in the different States, some time since took the responsibility of sending experts, equipped with the necessary instruments, to visit a number of the most important manufacturing establishments in various parts of the country, to test the consumption of steam power in each machine, with a view, of course, to determine what proportion was really utilized in the necessary operations of the concern, and how much was unconsciously or carelessly wasted. As a result of this examination nearly all were found to be wasting one-half of their engine's power in doing other than useful work. One prominent establishment was found to be wasting to the extent of 65 per cent of its fuel and power, another was wasting not less than 73 per cent, thus leaving the small amount of 27 per cent of the engine's power for practical use, and another eminent firm, noted all over the West, was using a 60-horse power engine of which not less than 55-horse power was consumed in dead work.

Starting Up a Set of Machinery.—One of the greatest difficulties in running machinery, says the Boston *Journal of Commerce*, especially when it takes some time to get well under way, is a proper method of applying power. The production in some places could be increased one-half if it were possible to bring up the speed gradually instead of slipping on a belt, and let everything start off with a jump. See how this gradually coming up to speed is made use of to this late day by having a heavy fly-wheel on the driving shaft with a belt just tight enough to set the machinery in motion. The driving pulley is left as smooth as possible, and the belt allowed to squeak and squeal for some time till the slipping comes to an end and the machinery reaches its required speed. A good cone-pulley counter-shaft of some kind will put an end to all trouble of this kind and bring the control of the speed within reach of the operator.

The Right Hight for a Vise.—Work at the vise is very often of a delicate character, requiring great exactness and nicety of touch. It is manifestly impossible for the workman to do his best under such circumstances if the natural play of the arms and the body is interfered with by a cramped or strained position. A skilled mechanic knows the intuitively and adjusts his vise experimentally until its hight suits him. But there is a simple and reliable method of getting the proper hight at once, which, we venture to say, few mechanics know. When standing easily at the side of the vise, the tips of the fingers should just touch the chin when the elbow is resting on the jaws of the vise. At that hight body and arms have free play, the touch is most certain and assured, and work far less fatiguing.—*Ironmongery.*

Running Belts.—It is said on good authority that a leather belt is tightened on one side just as much as it is slackened on the other when power is being transmitted by it, so that the sum of the tension on both the slack and tight sides always remains the same. This, says the Boston *Journal of Commerce*, would be true on almost anything else but a belt, or where the stretch is proportional to the amount of load opposed to it, but with belts there is so much of the belting coming in contact with the wheels that it interferes with the amount that is supported in the folds. One of the wheels is running on stretched leather, and the other on belting in its slackest state, changing the condition of the folds for every change in the load it is to carry.

"When a Belt Breaks," says a mule spinner, "take another and slap it on in place of it, and repair the broken one at leisure. I keep a spare belt for every machine in my room, cut the exact length, with the lace holes all made. Did you ever see me square the ends of a belt? I draw it out upon the floor, then double it up to bring both ends together, give it a half turn in twist at the same time to bring the same sides on top, and then out through both ends at once. It will be impossible to get a 'dog-leg' in that joint, no matter how much out of square it may be cut."

Useful Information.

To Strengthen Ropes.—It has been suggested by a French exchange that, in order to insure greater strength and consequently more safety in ropes used for scaffolding purposes, particularly in localities where the atmosphere is destructive of hemp fiber, such ropes should be dipped, when dry, into a bath containing 20 grains of sulphate of copper per litre of water, and kept in soak in this solution some four days, afterward being dried; the ropes will thus have absorbed a certain quantity of sulphate of copper, which will preserve them for some time both from the attacks of animal parasites and from rot. The copper salt may be fixed in the fibers by a coating of tar or by soapy water, and in order to do this, it may be passed through a bath of boiled tar, hot, drawing it through a thimble to press back the excess of tar, and suspending it afterward on a staging to dry and harden. In a second method, the rope is soaked in a solution of 100 grammes of soap per litre of water. The copper soap thus formed in the fiber of the rope is stated to preserve it even better than tar is capable of doing, which acts mechanically to imprison the sulphate of copper, which is the real preservative in the case.

To Estimate Lead in Tin Alloys.—To estimate lead in tin alloys, one gramme of the alloy, which has been rolled out into very thin sheets, is warmed gently with 20 cc. concentrated hydrochloric acid for about half an hour. Bromine water is now added until any undissolved metal is brought into solution, the excess of bromine is expelled by boiling the solution diluted to 100 cc. This is poured into a solution of 40 grammes sodium sulphydrate in 150cc. water, the latter being constantly agitated. After allowing the precipitate to settle, it is filtered and washed with very dilute ammonium sulphydrate. The precipitate and filter are treated in a porcelain dish with 10 cc. concentrated nitric acid, and, after the first violent reaction is over, 5 cc. sulphuric acid are added. Heat is now applied gently until the solution is almost colorless, and the precipitate filtered, washed and weighed. The weighed sulphate of lead is dissolved in basic ammonium tartrate, and any stanic oxide which it may contain is filtered, weighed and subtracted.

A Scientific Mosquito Bar.—Word comes from Paris of the invention of what may be called the alternating mosquito-bar. This consists of a mosquito-net made of extremely fine copper wire woven into a cloth, which is strong and at the same time almost as pliable as a netting made of vegetable fiber. This net is made in the usual form of a canopy, and falls in shining folds about the bed. In the dome of the canopy hangs a small electric lamp. Wires connect the netting with a weak pile battery placed under the bedstead, and by means of a converter are carried into the lamp. The lighted lamp attracts the attention of every mosquito in the neighborhood, and he comes sailing over and lights upon the wire canopy. The battery presses the button, and the mosquito does the rest. M. Scherer, the inventor, says that on the first morning after his net had been put into use, his servant took up 3 22 litres, or nearly three quarts of dead mosquitoes.

The Philosophy of It.—If a teaspoon is placed in an empty glass, boiling hot water can be poured into it without breaking. A fork will not serve the purpose at all, as it is something in the shape of a spoon that concentrates the heat of the boiling water in itself. This is worth knowing by hot water drinkers, as the water is far more palatable in a glass than in a cup.—*Ex.* [The philosophy of our contemporary is probably incorrect. The immunity of the glass from being cracked arises from the fact that the water falling upon the spoon is more largely distributed over the inner surface than when it falls upon the tines of a fork. The glass is crooked only when rapid expansion of the inner surface is produced by the hot water falling upon a small area of surface. The broad surface of the spoon distributes the water—the narrow surface of the tines of the fork fails to do that.—Eds. Press.]

Several Ways of Preventing Ice from Melting too Rapidly.—There are three or four things that will help to keep the precious nugget of ice from melting away, if the housekeeper will only remember them. One is that to keep ice warm is the way to keep it cold. A piece of ice in a pitcher, with a pail over the pitcher and a rug over the pail, will keep all night. A piece of ice in a refrigerator, covered with a snug white blanket, will cheat the greedy iceman every day, and snap saucy fingers at the milk that does not dare to get sour or the beefsteak that dares not fail. These things are admirable in their way, and should be in every hathand, but the greatest trick of all is newspapers. With plenty of newspapers above, below and on every side, the way a piece of ice will keep is a joke.—*Chicago Herald.*

A New Military Drill.—One of the features of military drill in the Russian army is the training of soldiers to swim in battalions, at the same time using their weapons. A large force of infantry swam across a wide lake in full marching order, with the help of fascines made of reeds and rushes or of inflated sheepskins. At the same time they kept up a lively fire on the boats of a supposed enemy who were disputing their passage.

Imitation of Ivory.—A composition for imitation of ivory, for decorative purposes, is made by gently boiling half an ounce of isinglass in a half pint of water till dissolved, then straining and adding flake white (basic nitrate of bismuth and a very little Naples yellow, oxide of lead and satinone). This is to be mixed with rice water and starch powder. Add to the work a final coat, and rub this with fine sandpaper to take off the gloss.

Engineering Notes.

Preventing the Overflow of the Mississippi.

The late extraordinary rise in the Mississippi river, and the imminent danger threatened therefrom, seems to have induced a new and more resolute determination to adopt some preventive measure for such danger in the future. It appears to be universally acknowledged that some more adequate engineering means of defense than the present system of levees for retaining the waters within their natural barriers should be devised and adopted. There are several alternative plans—namely, the provision, in the lower course of the river, of outflow channels, that may be utilized in seasons of threatened floods, and when the volume of the river becomes dangerously swollen; and the provision, along the headwaters of the great river and its tributaries, of great impounding basins, covering great areas, and capable of retaining temporarily the floodwaters, which would be permitted to flow off gradually without endangering the country below, as at present, by its sudden accession to the river.

As the levee system is already in operation for hundreds of miles along the course of the Mississippi, having been developed year by year at enormous cost to the Government, it would be the wisest policy doubtless to maintain these artificial barriers in their present extent, and to supplement their protecting influence by both the engineering expedients above suggested. With these precautions, it is almost assured that the annual destructive floods of the lower Mississippi country would be avoided in the future. The use of embankments alone has been found, in the experience of all countries where the system has been tried, to be extremely hazardous. The gradual rise of the bed of the stream, caused by the deposition of silt, necessitates either continual dredging or the continual elevation of the walls of the embankment.

In China where this primitive system has been practiced from time immemorial, the embankments have had to be carried up so high from this cause, that the surface of the rivers are many feet above the level of the surrounding plains, and the frightful disasters that are periodically reported as being caused by the overflow of the great rivers of that country, can readily be understood. The subject of applying proper remedial measures to control the flow of our great river, it is gratifying to note, is now receiving the anxious attention of the Government engineers, and adequate measures for accomplishing this result will doubtless be adopted and carried into execution at once.

Possibility of the Siberian Railway.—Few people are aware of the enormous possibilities of the great Siberian railway. This road will be the largest single line of railway in the world. The distance from the Ural mountains to its eastern terminus is 4500 miles. Northern Asia is a remote country, yet the construction of the Trans-Siberian railway is a matter in which our great Northwest is directly concerned. It will open up a vast area peculiarly adapted to wheat-raising, a country where the virgin soil and cheap labor will combine to stimulate an immense production. It is quite possible that the Siberian railway will be open for traffic within five years, and agricultural immigration will then be attracted by liberal offers of free land. The Siberian railway will connect with the railroad systems of Russia proper, Finland, Sweden and Norway. Siberia will then become one of the chief grain exporters of the world. We trust that by this time the United States will be well out of the wheat-exporting trade, and that our home consumption will demand the wheat crop of the United States. No nation is so poor as that which is obliged to export raw materials and agricultural products to pay for its imports.

The Ship Railway over the neck of land which separates the head of the Bay of Fundy from the waters of the Gulf of St. Lawrence has been graded for 14 out of the total of 17 miles, and all the rails have been delivered on the line. It is calculated the raising and transfer over the 17 miles can be done in two hours, while the distance saved by the overland trip is about 500 miles. It is expected the ship railway will be finished next year.

The longest railroad bridge span in the United States is the cantilever span in the Poughkeepsie bridge over the Hudson river, 548 feet.

TABLE OF CONTENTS.

EDITORIALS.—Amalgam Strainers, 49. Passing Events; Examining Stock Board Mines; Academy of Sciences; White Lead Shipments; The Mount Lyell Glacier; Copper Statistics, 56. The Central San Juan Region, 57.

ILLUSTRATIONS.—Table with Bags for Straining Mercury; Wooden Amalgam Safe; Iron Amalgam Safe; Quicksilver Amalgam Safe; The Mount Lyell Glacier in the Sierra Nevada, 49. Map of the Central San Juan Area, 57.

CORRESPONDENCE.—Ancient River Channels; Virond District, Montana; The Gold Belt of Northern California, 50. San Bernardino County, 51.

MECHANICAL PROGRESS.—Philosophy of the Injector; Improvement in Soft-back Steel; Rattling of Machinery; Determining the Hammer Blow; Goods from Dies by Hydraulic Pressure; A Chimney that will Draw; Steam Thermometers; Miscellaneous, 54.

SCIENTIFIC PROGRESS.—Magnetism of Steel Cylinders; Meteorological Notes; A New Fuel; Phosphorescent Infection; The Artificial Production of Rain; Boiling of Water not a Guarantee of Purity; Imponderable Elements; Rapidity of Thought; Zinc Deteriorated by Brickwork; Structure of Flame; Minuteness in Astronomical Work, 54.

GOOD HEALTH.—Health of the State; Danger from Electrical Currents; Sudden Starts, Jerks, Etc., While Asleep; Nutritive Value of Foods; Bacilli in Celery, 55.

SHOP NOTES.—Wasting Power; Starting Up a Set of Machinery; The Right Hight for a Vise; Running Belts; Miscellaneous, 55.

USEFUL INFORMATION.—To Strengthen Ropes; To Estimate Lead in Tin Alloys; A Scientific Mosquito Bar; The Philosophy of It; Several Ways of Preventing Ice from Melting too Rapidly; A New Military Drill; Imitation of Ivory, 55

ENGINEERING NOTES.—Preventing the Overflow of the Mississippi: Possibility of the Siberian Railway; Miscellaneous, 55.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Wyoming, 52-53.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 62.

MARKET REPORTS.—Local Markets, Eastern Metal Markets, 62.

Business Announcements.

Passing Events.

It is worthy of note that the new mining stock exchanges recently established at several mining centers have adopted a rule that all mines listed shall be first examined to see whether or not they are bona fide properties or "wild-cats." This ought to have been done in San Francisco years ago.

The heaviest fine ever assessed upon a mining company in this State for "contempt" has been imposed upon the Omega Mining Company of Placer county, by Judge Sawyer. The usual fine has been $500, but this time $3000 is imposed.

The mining outlook in Nevada is greatly improved and many mines are again producing. The favorable silver legislation has had much to do with this.

Very active steps are being taken by the Native Sons of the Golden West toward making a grand success of the coming celebration of the 40th anniversary of the admission of California into the Union. San Francisco will be in gala attire during the celebration and thousands will visit the city from the Interior.

A test suit has been commenced in Virginia, Nevada, against the Crown Point Mining Company, to determine whether or not the Comstock Tunnel Company can legally collect the royalty on ore due the Sutro Tunnel Company.

Examining Stock Board Mines.

The several Stock Exchange Boards recently established at various points, such as Kansas City, Helena, Butte, Spokane Falls and Salt Lake City, have adopted new rules for the listing of stocks. It is stipulated that upon a stock being listed a sum of money shall be deposited to defray the cost incurred by the Exchange Board in sending an expert to report upon the property, no exception being made to this rule, save in regular dividend-paying properties. The Exchange Board furthermore reserves the right at any time, to send an expert to examine any property on the list, all such reports to be open for the inspection of all those who may have the privilege of the board. In Montana the fee for listing mining stocks has been fixed at $50 for the first year, and $25 per annum thereafter.

This is a very wholesome rule, and if it is only carried out, it will make the new stock boards much more satisfactory to the public than the old ones. Its adoption has been urged upon our local boards for years past, but they have seen fit to ignore the plan. There is really no guarantee at all offered by the boards that the mines are what they are represented, so that the public has suffered more or less by investing in wild-cat securities. As long as the company paid the listing fee it has been all right, though some sort of office or committee investigation is supposed to be made. There has, however, never been any pretense of actually making an expert examination of the mine itself.

Of course there is still liable to be misrepresentation in such matters where small listing fees are supposed to cover an examination also, for expert investigations are usually expensive. Still, if the Stock Boards send a representative to the mine itself, he can form a pretty good idea about the property, and at any rate can say whether it is a prospect or a mine. On his report, when made public, people can know something about what they are investing in. Such a plan, honestly carried out, will do much to modify existing evils, especially if an expert can be sent at any time it is considered necessary. In such cases he could block dishonest deals and expose fraudulent strikes. It will make mine manipulators more careful, to say the least. Now, if the companies will also adopt a rule providing for black-listing any company having as its manager or director persons who have been found to be tricky in such dealings in other companies, still further progress toward purifying mining stock transactions will be made.

THE MOLDER'S STRIKE.—The examination of James W. Kerr, proprietor of the Occidental Foundry, for killing Edward Cogan, a molder's apprentice, is now going on in the Police Court. The circumstances of the case have already been detailed in the PRESS. A few men are "captured" by the Molder's Union every week, and others are brought from the East by the foundrymen to take their places. The Novelty Iron Works, which were closed before the strike began, and whose owner was not a member of the Iron Founders' Association, have been reopened by members of the Molder's Union and a few men have gone to work there.

FINED FOR CONTEMPT.—A fine of $3000 was this week entered in the U. S. Circuit Court against the Omega Water and Mining Co. of Placer Co. The Omega was one of the hydraulic mining companies enjoined, and it was cited to appear and show cause why it should not be punished, and the Master in Chancery decided that the company had not shown cause for its action. The customary punishment in such cases is $500, but Judge Sawyer in this case levied the heaviest fine—$3000—ever assessed upon mining companies in this State for contempt.

THE ELECTRICAL SOCIETY.—At the meeting of the California Electrical Society this week, Prof N. S. Keith informed the members that a library and laboratory would be necessary to an intelligent prosecution of the work commenced, and that he would solicit contributions for this purpose among those who would be willing to render the society some assistance. He thought that at least $150 should be expended on standard works for the use of the members, and that he could easily raise that amount.

Academy of Sciences.

At the regular meeting of the Academy of Sciences on Monday last, President H. W. Harkness was in the chair. Owing to lack of quorum the three proposals of membership which had been made were laid over to a future meeting.

G. P. Rixford presented the society with some specimens of soda, flies and larvæ, taken from Soda Lake, in the Owen's River valley, and white marble from Inyo county. With reference to this marble, it was stated that D. O. Mills had entered into a contract to use the same in the construction of the first two stories of his new building on Montgomery street.

Thomas C. Johnson, a graduate of the Edinburgh University, through Captain I. E. Thayer presented five cases of rare coral from the Navigator group of islands.

Dr. H. C. Bolton, General Secretary of the American Association for the Advancement of Science, spoke on the history of the Association, and said that the next meeting would be held on the 19th of August in Indianapolis, and would continue one week. This will be its thirty-ninth anniversary, and the incoming President will be George L. Goodale, the well-known botanist of Massachusetts. He hoped the day might not be far distant when an annual meeting might be held here. It was suggested by some of the members present that an effort be made to be have it held in this city two years hence.

White Lead Shipments.

Last week another large shipment of white and red lead was made by Whittier, Fuller & Co. to New York. The comparatively higher prices ruling at the East for white lead makes these ventures a source of profit, and at the same time increases the consumption of raw material, which is quite a desirable item for the mines on this coast which make a large lead output. As the Eastern demand for white lead increases, naturally the consumption of lead will be enlarged here. The factory in this city is a large and well-equipped one, but most of its product has been heretofore consumed here. The possibility of Eastern shipment enlarges its scope and should eventually increase its capacity.

While California itself produces comparatively little lead ore, large quantities come in here from other Pacific Coast States. The mines in Inyo county and thereabouts will be put on their old productive footing before long. The Selby Lead Works, shot tower and Whittier, Fuller & Co.'s white and red lead works are quite flourishing California institutions.

ALVAN CLARKE, the famous telescope-lens maker, states that it will cost an extra $10,000 to grind and polish the big lens for the Spence telescope for the Southern California University, if he does it in this State instead of at his works at Cambridge. Mr. Clarke will visit California in August.

THE Board of Supervisors of Sacramento Co., decline to issue a call for an Anti-Debris Conference but will participate if the Anti-Debris Association calls it. The proposed convention is to consider matters growing out of the alleged operation of hydraulic mines on the tributaries of the Sacramento river.

THE complaint enjoining the county of Yuba and Sheriff Dunster from selling the North Bloomfield hydraulic mine, to satisfy an unpaid contempt fine of $500, alleges that the judgment for contempt was in excess of the jurisdiction of the Superior Court of Yuba county and void.

THE Anaconda Company and the Montana Union Railroad have fixed up a 30-day truce, and several hundred miners who were laid off will return to work at once.

WE are indebted to U. S. Senator A. P. Gorman for a pamphlet on "The Mississippi and its Forty-four Navigable Tributaries," by Alex. D. Anderson.

MR. J. A. FERSON has resigned his position as superintendent of the Union and Keystone Copper mines, at Copperopolis, Calaveras Co.

THE San Francisco Stock Board has declared a dividend of $100 to each member.

The Mount Lyell Glacier.

The fact that the Sierra Nevada bears the record of having formerly been the source of immense glaciers has been recognized by all geologists who have visited the region, but no systematic study of the glacial phenomena displayed throughout a large portion of the range has been carried out. An arduous task, but one of fascinating interest here awaits the geological explorer.

The labors of the geologists of the California Geological Survey has shown that glaciers of great magnitude existed on the high peaks about which Kern and Kings rivers rise. Here are the most southern glacial records that have been reported in the Sierra Nevada, but the extreme southern limit of the glaciated regions has not been definitely determined.

A summary of what is known concerning the living glaciers of the Sierra Nevada will be found in an essay on the existing glaciers of the United States in the Fifth Annual Report of the U. S. Geological Survey. The present ice bodies of the Sierra are small and are but miniature counterparts of the glaciers found in many other regions. They occur mostly in deep cirques on the north sides of the more lofty peaks, and with few exceptions flow northward. Observations made during the survey of the Mono basin show that there are nine small glaciers within the area draining into Mono lake.

At the head of Tuolumne canyon, on the north side of Mt. Lyell, is the largest glacier in the neighborhood of Lake Mono. The accompanying view, taken from the Geological Survey Report, will obviate the necessity of a lengthened description. The moraines now forming about the foot of the glaciers are shown. Each of the ice bodies observed occurs at the head of a deep canyon which was once filled by a magnificent trunk glacier. The largest of these ancient glaciers originated in the amphitheater on the side of Mt. Lyell, and flowed down Tuolumne canyon, forming a veritable river of ice, over 2000 feet deep near its source and about 40 miles long. The present glaciers are perhaps the shrunken remnants of the ancient ice rivers, but they may have had a fresh beginning within quite recent times.

Copper Statistics.

The steady improvement in the position of copper fully bears out the position taken by the MINING AND SCIENTIFIC PRESS about one year ago. The changed condition for the better is not based on a lessened output, but a steady, if not rapid, absorption of accumulated stocks during the French syndicate deal. According to latest English mail advices, for the 12 months ending with June, the stocks, supplies and deliveries in England and France were as follows:

	Stocks. Tons.	Price of Bars.	Supplies. Tons.	Deliveries. Tons.
1890.....	72,493	58¾.	114,892	154 088
1889.....	111,689	41¾.	113 137	73,091
1888.....	72,243	81/.	114,395	94,124

Notwithstanding the large stocks in June, 1889, and heavy deliveries from July 1, 1889, to June 30, 1890, the stocks were only 23,000 tons in excess of the quantities held in stock when M. Secretan and his friends began operations, for which they have since suffered. At the same time bar copper recovered in the London market from £38 in April of 1889 to over £58 at the close of June, 1890.

The statistical position of American copper is equally gratifying. The output of the Lake Superior mines first half the present year aggregated 45,000,000 pounds, or 3,000,000 pounds more than during the like time in 1889. Not only the entire output and considerable of the carry-over has been consumed, but the increased products of other mines have gone into consumption. A year ago there was held in Europe the equivalent of 21,566 tons fine American copper, but the first of the present month there were not 12,000 tons held abroad.

A MURDER occurred on the 1200-ft. level of the Savage mine, on the Comstock, last Sunday. Patrick Crowley, a miner, struck Wm. Nichols, shift boss, on the head with an ax and killed him.

THE Morgan mill has been running steadily on Con. Cal. and Virginia ore ever since October, 1886, and has cleaned in that time nearly 200,000 tons, producing over $4,000,000 in bullion.

The Central San Juan Region.

The accompanying topographical map of the central San Juan region, Colorado, is based upon surveys of Wheeler and Hayden, in part, but embodying many features of the work of Theo. B. Comstock, who has described the section in question before the American Institute of Mining Engineers. The map contains numerous details, with the roads, mines, etc. In the other districts, aside from particular limited areas, there is not great difficulty in laying out mining work intelligently from the outset, for it is quite possible to plot the excavations in advance from instrumental surveys. In the Red mountain area, however, this is commonly impossible. The deposits are not in well-defined linear crevices, but they occupy irregular cavities, apparently related in some general manner (as along a N. E.—S. W. trend) to deep-seated fissures. The vein-stuff is far from uniform, and it is usually of the most complex character. Almost all known mixtures of the sulphides, arsenides and antimonides of iron, lead, copper and zinc are found mingled indiscriminately with varying percentages of the precious metals.

The country is peculiar in the great number of hot springs. The ores are by no means such as could be readily obtained from the adjacent rocks, nor were the hot springs confined to one member of the volcanic series in aggregations of the same kind. It is true that the rhyolitic exposures show different alterations usually from what are found in the hot spring deposits in the trachyte, but there is not a corresponding difference in the percentage of the precious metals, while there are excellent veins in rhyolite which have not been subjected to this recent thermal ocean action. In this small area are locked more secrets connected with the alterations of the tertiary veins than can be solved in many lifetimes, and fortunate indeed will he be who has the best opportunity to investigate here.

The American Belle, Grand Prize and other mines are in gigantic geyser mounds; the Yankee Girl, Guston, Congress, etc., appear to

occupy the bowls of non-sintering springs, and nnmerous other properties show direct relations to the elevations and depressions which give that peculiar aspect to the region which is indescribable, but which would be recognized at once by any careful observer who had ever visited a similar tract of modern origin.

Text of the Silver Bill.

The bill recently passed by both Houses of Congress and signed by the President, and which is now part of the statutes, reads as follows:

SECTION 1. The Secretary of the Treasury is hereby directed to purchase from time to time silver bullion to the amount of 4,500,000 ounces, or so much thereof as may be offered, in each month, at the market price thereof, not exceeding $1 for 371 25 100 grains of pure silver, and to issue in payment for such purchases of silver bullion treasury notes of the United States to be prepared by the Secretary of the Treasury, in such form and of such denominations, not less than $1 nor more than $1000, as he may prescribe, and a sum sufficient to carry into effect the provisions of this Act is hereby appropriated out of any money in the Treasury not otherwise appropriated.

SEC. 2. That the Treasury notes issued in accordance with the provisions of this Act shall be redeemable on demand in coin at the Treasury of the United States, or at the office of any Assistant Treasurer of the United States, and when so redeemed may be reissued, but no greater or less amount of such notes shall be outstanding at any time than the cost of the silver bullion and the standard silver dollars coined therefrom then held in the Treasury, purchased by such notes, and such Treasury notes shall be a legal tender in payment of all debts, public and private, except where otherwise expressly stipulated in the contract, and shall be receivable for customs, taxes and all public dues, and when so received may be reissued; and such notes, when held by any national banking association, may be counted as a part of its lawful reserve; that upon demand of the holder of any of the Treasury notes herein provided for, the Secretary of the Treasury shall, under such regulations as he may prescribe, redeem such notes in gold or silver coin at his discretion, it being the established policy of the United States to maintain the two metals on a parity with each other upon the present legal ratio or such ratio as may be provided for by law.

SEC 3. That the Secretary of the Treasury shall each month coin 2,000,000 ounces of the silver bullion purchased under the provisions of this Act into standard silver dollars until the 1st day of July, 1891, and after that time he shall coin of the silver bullion purchased under the provisions of this Act as much as may be necessary to provide for the redemption of the Treasury notes herein provided for, and any gain or seigniorage arising from such coinage shall be accounted for and paid into the Treasury.

SEC. 4. That the silver bullion purchased under the provisions of this Act shall be subject to the requirements of existing law and the regulations of the Mint service governing the methods of determining the amount of pure silver contained, and the amount of charges or deductions, if any, to be made.

SEC. 5. That so much of the Act of Feb. 28, 1878, entitled "An Act to authorize the coinage of the standard silver dollar and to restore its legal tender character," as requires the monthly purchase and coinage of the same into silver dollars of not less than $2,000,000 nor more than $4,000,000 worth of silver, is hereby repealed.

SEC 6. That upon the passage of this Act the balances standing with the Treasurer of the United States to the respective credits of national banks for deposits made to redeem the circulating notes of such banks, and all deposits thereafter received for like purpose, shall be covered into the Treasury as a miscellaneous receipt, and the Treasurer of the United States shall redeem from the general cash in the Treasury the circulating notes of said banks which may come into his possession, subject to redemption; and upon the certificate of the Controller of the Currency that such notes have been destroyed, and that no new notes will be issued in their place, reimbursement of their amount shall be made to the Treasurer, under such regulations as the Secretary of the Treasury may prescribe, from an appropriation hereby created to be known as "National bank notes' redemption account;" but the provisions of this Act shall not apply to the deposits received under Section 3 of the Act of June 20, 1874, requiring every national bank to keep in lawful money with the Treasurer of the United States a sum equal to 5 per centum of its circulation, to be held and used for the redemption of its circulating notes, and the balance remaining of the deposits so covered shall, at the close of each month, be reported on the monthly public debt statement as debt of the United States bearing no interest.

SEC. 7. That this Act shall take effect 30 days from and after its passage.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, *or beyond the time he intends to pay for it*, let him not fail to write us *direct* to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

Sylvania District, Inyo County.

EDITORS PRESS:—Thinking that news from this new California camp may interest the mining portion of your readers, I send you the following items: The camp proper, viz: the works, boarding-houses, dwellings, etc., are located in Inyo county, about 46 miles east from Big Pine Station on the Carson & Colorado railroad, almost at the boundary line between California and Nevada, the furnace now building being 500 feet inside the California line.

The Sylvania Mining Co. is composed of Andrew Fife and J. and E. Crocker of Big Pine and is pushing work vigorously to finish the furnace (a 40-ton Pacific water-jacket) and further develop the two company mines, the Liberal and the Climax, which were purchased from W. F. Kincaid. It is thought the furnace will be ready to blow in about the first of August.

The ore developments in the Liberal mine are pronounced by expert galena men to be astonishing, and never before have such vast bodies of galena silver ore been developed with such ease and little expense. The mine shows 12 feet in width of solid cube galena of unknown depth; but already developed to the extent of several thousand tons ready to stope and raise. The Climax shows a chimney of ore on the surface, and is being exploited by a tunnel running to strike the deposit at a depth of 250 feet.

This mining district is a large one, and is comparatively unprospected, except the galena belt on which are about 25 locations exclusive of the two owned by the company. Four of these claims owned by Mr. Frank Buser and son, are pretty well developed, two of them showing very large deposits of cube galena and gray carbonates. Reimas & Co. struck a fine body of carbonate ore in their claims a few days since. In fact there is not a claim upon which work has been done to any extent but what shows fine ore deposits.

The limestone belt (porphyritic lime) is a very large one and extends for miles from northwest to southeast.

There has been on the part of some persons a seeming desire to keep this camp in the background, and representative mining men have not been in to examine the mines.

Six years ago an expert galena miner spent several weeks here, and reported very favorably upon the district, saying that some time in the near future it would be one of the largest and most lasting of all the great galena camps, but not until both silver and lead advanced in price. That time seems now to have come along with the increasing price of the two metals. Our ore is high grade, averaging about 65 ounces silver, and over 50 per cent lead, and one mine belonging to Buser, from which a great deal of ore has been shipped carries over 100 ounces silver, $18 gold and 70 per cent lead.

The camp has only been started for two months, and now has a population of 150, almost every one being employed by the company. Several families have come in lately. Lumber is hard to get, owing to the heavy winter snows in the lumber regions of the Sierras.

A mail line from Big Pine will soon be started, putting the camp in connection with the inside world. B.

Sylvania, via Big Pine P. O., Inyo Co.

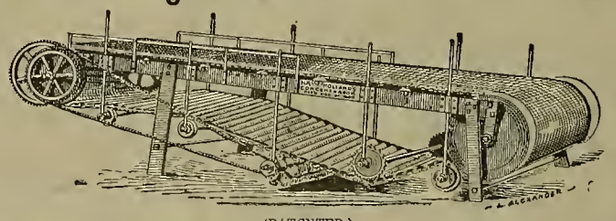
Holland's Corrugated Woolen Belt Ore Concentrator



(PATENTED.)

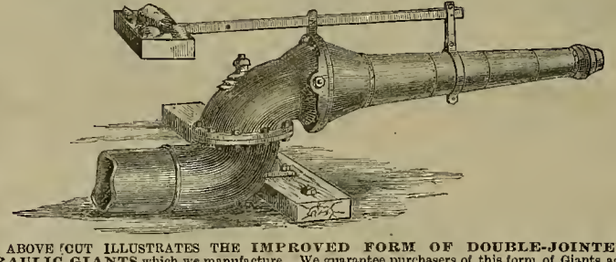
Will save more fine gold and flour quick than any concentrator ever made. Will also concentrate cinnabar and gale a ores perfectly and with economy. The invention is new and possesses all the advantages of the old blanket system, while avoiding its faults by the use of the Corrugated Woolen Belt, which is thoroughly cleaned by means of a revolving brush connected and operated with the machine. It is simple in construction and cannot get out of order. Small power is required to run it.

Price of Concentrator for Ten-Stamp Mill, $1000; for Five-Stamp Mill, $600.

For Circulars, address H. P. HOLLAND, 2322 Folsom Street, San Francisco, Cal.

Concentrators on exhibition at WILLIAMS & ORTON'S, Manufacturers, 315 Mission St., S. F.

IMPROVED FORM OF HYDRAULIC GIANTS.



THE ABOVE CUT ILLUSTRATES THE IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture. We guarantee purchasers of this form of Giants against all costs, expenses or damages which may arise from any adverse suits or actions at law. We are further prepared to furnish Single-Jointed Giants when required. Prices, discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent on application.

FIRST and STEVENSON STS., S. F.

The Redwood Forest.

In size of individual specimens, the redwood (*Sequoia sempervirens*) ranks next to its relative, the big tree of the Sierra Nevada (*Sequoia gigantea*) and the eucalyptus of Australia; but if we take the average size of the trees and the density and extent of the forest into consideration, the redwood is the grandest of the world's forest trees. It belongs to the Coast Range of Northern California. A few straggling groves only are to be found below Monterey bay, and it does not extend far into Oregon. The largest body commences at the mouth of Russian river and extends into Oregon. Another large forest lies south of San Francisco, in Santa Cruz county. The widest portion of the great or northern body of redwood timber lies in Mendocino county, between Ukiah and the ocean. Here it is by air-line 25 miles wide—a vast, unbroken forest with branches extending inward up the canyons. The peculiarity of the redwood is its love of moisture, which means here fog. The fog banks rise from the Pacific and flow inland like a great level sea of vapor. The lower mountains next the coast are enveloped, and farther on it fills the canyons, leaving the high mountains to rise like islands out of it. Still farther inland only the lower portions of the canyons are filled with fog. At times the sea of fog will rise so high that it engulfs nearly the whole section back to the high dividing range of mountains which is the watershed between the streams running directly into the ocean and those which flow into the Russian and Eel rivers, which extend for a long distance parallel to the coast line. Then the fog goes pouring through the passes in actual rivers of vapor, which run down the canyons toward the interior. Strangely enough, it always returns as it goes.

Now, with this sea of fog in mind one can locate the redwood belt most accurately. Near the coast on the lower mountains, and everywhere, the densest forest is almost exclusively of redwood. Farther inward sweeps the same dense forest on the lower mountains and in the canyons at the same hight. Redwood forest is still on all the mountains, but of smaller trees, and the greater the elevation the more largely it is mixed with Douglas spruce (Pseudotsuga taxifolia) and the tan bark oak (Quercus densiflora). Still farther inland near the watershed spoken of before, redwood only grows in canyons, and the mountains are either open grazing land, covered with oak and fir, or with that dense low growth known as chemisal (Adenostoma fascicularis). Over the watershed, down those canyons where the fog pours over, there still are groves of redwood, well confined to the moist banks close to the courses of the streams; while up the broad canyons of Eel and Russian rivers the fogs roll and nourish the life of the grandest of all of the redwoods till they are held back by the heat of the interior.

The redwood is not only a lover of moisture, but, to an extent hardly to be believed unless seen, a condenser and conserver of moisture. The tops reach high into the sea of vapor, and a constant precipitation from them like rain takes place. Last summer I was on the coast during a foggy time, and I remember that while the roads were dry and dusty, in the clearings under the redwoods the water had been precipitated till it stood in puddles and formed mud holes. This abundance of moisture causes the densest of undergrowth, which only continual fires make passable. Hazels, huckleberries, various ceanothuses, ferns of large size in the greatest profusion, with large bushes of Rhododendrons and numerous other plants, make the forest floor a perfect tangle in the moister portions. The list of herbaceous plants here is not large, but they are delicate and beautiful. The glossy leaves of Vancouveria hexandra form dense masses; an Orchid, Goodyera Menzieger, is common, and in the spring Trillium ovatum and the Erythroniums are plentiful, and so is the lovely Clintonia.

Of small ferns, only the beautiful Adiantum pedatum, the Maiden-hair, is common; but there are several species of Aspidium and the Woodwardia, and Brake is everywhere, making in the cleared forest a solid mass four or five feet high. I have seen acres of the Brake seven or eight feet high, where a man could only crawl through the tunnel-like paths. Every year or two forest fires sweep through this forest tangle, but it springs up again with renewed vigor. The redwood, unless very young, is not injured by fire. Its thick bark protects it, and often trees will be seen which had every limb stripped by the fire, putting out a mass of foliage from top to bottom. No name could be more appropriate than sempervirens, for it possesses wonderful vitality. A tree cut throws up hundreds of strong sprouts, and a stump is only killed by repeated burning. Fallen trees will often grow along the whole length of the stems, and throw up sprouts from the upturned roots, and I have seen sprouts six or eight feet high from logs. The commonest care would ensure the perpetuity of these grandest of forests.—*Carl Purdy, Ukiah, Cal., in Garden and Forest.*

A CURIOUS FACT.—In some recent experiments the curious fact was established that electrifying a jet of steam decreases its transparency.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING JULY 15, 1890.

432,116.—EXCAVATING APPARATUS—H. Casebolt, S. F.

432,373.—DOUBLE-ACTING PUMP—J. M. Clark, Colfax, Wash.

432,119.—WINDOW-SASH HINGE—G. D. Crocker, Oakland, Cal.

432,021.—CULTIVATOR—Wm. Davis, Los Angeles, Cal.

432,121.—SUPPLYING GASES AND LIQUIDS TO MOVING VEHICLES—L. J. De Puy, Phœnix, A. T.

432,133.—WASHING MACHINE—W. H. Gilstrap, Pixley, Cal.

432,307.—LAWN-MOWER ATTACHMENT—R. R. Grimes, Santa Monica, Cal.

432,162.—COVERING FOR PIPES—H. M. Hanmore, Santa Cruz, Cal.

432,140.—SAFETY RELIEF VALVE—A. D. Kilborn, Oakland, Cal.

432,420.—COTTON HARVESTER—J. H. Masters, Stockton, Cal.

432,191.—WIRE-ROPE TRANSMISSION—B. McIntire, S. F.

432,065.—LAWN-MOWER ATTACHMENT—W. C. McQuillen, Los Angeles, Cal.

432,320.—FRUIT-BOILER—Alice W. Miller, Ashland, Or.

432,127.—FUSE-CAP FASTENER—N. W. Moody, Fresno, Cal.

432,146.—WINDMILL—O. W. Parker, Oakland, Cal.

432,336.—EXPLOSIVE COMPOUND—S. D. Smolianinoff, S. F.

432,150.—VEHICLE RUNNING GEAR—Geo. A. Stom, Golden Gate, Cal.

432,217.—SAND-BAND—Jas. Van Curen, Ferndale, Cal.

The following brief list by telegraph, for July 8, will appear more complete on receipt of mail advices:

California—Daniel Best, San Leandro, variable eccentric; Francis A. Bishop, San Francisco, rotary watermeter; Harrison I. Briggs, assignor of three-fourths to A. Myers, J. B. Birdsell, South Bend, Ind. and W. T. Carskadon, Los Angeles, split pulley; Oliver C. Christian, Brodie, steam food cooker; William T. Cottier, Oakland, ventilator; Evert Dewitt, Hanford, windmill; James C. Gould, San Jose, railway cattle guard; George F. Gray, San Francisco, cable railway construction machinery; R. Hall, San Francisco, salve; Arthur C. Harper and C. S. Hamlin, Los Angeles, machine for punching and riveting; Wallace S. Holland, Pasadena, sash or blind holdsr; Robert L. Hottel, Cedarville, middlings purifier; Byron Jennings, San Jose, conduit electric railway; Howard Legge, San Francisco, pencil box; Thomas McConnell, San Francisco, loading elevator; Edward C. Sessions, Oakland, street railway car. Washington—Syrsling W. Baker, Tolalo, stump-puller; Isaac N. Groves, Montesano, lifting jack. Oregon—Charles C. Hogus, Corvallis, water-wheel. Utah—Bernard R. Mayheck, Salt Lake City, assignor of one-half to A. White, Kansas City, Mo., toilet fan.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

VEHICLE RUNNING-GEAR.—Geo. A. Stom, Golden Gate, Alameda Co. No. 432,150. Dated July 15, 1890. This vehicle running-gear consists of a series of elastic springs connecting the front and rear axles, and so disposed as to allow the front axle to be turned without the interposition of a bolster or fifth-wheel.

WASHING MACHINE.—Willis H. Gilstrap, Pixley, Tulare Co. No. 432,133. Dated July 15, 1890. This consists in the novel construction of the air-chamber at each end of the rocking vessel, the guards or screens in said ends, and the rocking connection between said vessel and its bed. The objects of the invention are to provide a washing machine in which the clothes will be limited in their movement within the vessel containing them before reaching the ends of said vessel, while the water will pass through and beyond them; to provide for a chamber at each end in which the air is compressed, and out of which it is driven into and through the clothes in order to better agitate and expand them; to provide a simple and effective means for guiding and holding the rocking vessel on its bed, and generally to provide a washing and churning machine in which, by reason of the peculiar construction of the ends, a perfect agitation of the contents is had.

SAFETY RELIEF-VALVE.—Alden D. Kilborn, Oakland. No. 432,140. Dated July 15, 1890. This invention consists in the combination, with the safety-valve casing, cup-shaped adjusting end and tension spring, of a valve and valve-seat having expansion chambers or grooves formed in the meeting faces thereof. This is an improvement on a patent obtained by the same inventor March 27, 1883, No. 274,787.

SAND-BAND.—James Van Curen, Ferndale, Humboldt Co. No. 432,217. Dated July 15, 1890. This invention relates to the class of devices which are applied to the ends of the wheel-hub in order to protect the bearing or journal from the entrance of dust, sand or mud. The object is to provide a simple and practical protector of this class which is adapted to be readily applied and used in connection with any sized hub.

SELF-LOADING MECHANISM FOR WIRE-ROPE TRANSMISSION.—Bartlett McIntire, S. F. No. 432,191. Dated July 15, 1890. This invention relates to the general class of mechanism included in the system of transportation by means of wire rope, said system being commonly employed in mines where the ore is placed in carriers suspended by clips from a traveling rope or cable, whereby the carriers are transported to suitable points and distances. The object of this invention is to provide for automatically loading the carriers of the endless rope.

DEVICE FOR SUPPLYING GASES AND LIQUIDS TO MOVING VEHICLES.—Louis J. De Puy, Phœnix, Arizona. No. 432,121. Dated July 15, 1890. This invention relates to that class of apparatus adapted for taking gas or liquid from a suitable main or supply receptacle into a vehicle while in motion. The particular purposes to which the invention may be applied are various. Among other things, it may be used for railways adapted to be propelled by water, air or gas, and it is also useful for supplying a moving vehicle with any liquid not necessary for its immediate propulsion, but simply for transportation, such as supplying a tank with oil as the vehicle moves.

WINDMILL.—Orin W. Parker, Oakland. No. 432,146. Dated July 15, 1890. This patent covers certain details of construction in connection with the regulating apparatus for relieving the wheel in case of too much wind.

Assessment Notices.

GRAY EAGLE MINING COMPANY—Location of principal place of business, San Francisco, California. Location of Works, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 1st day of July, 1890, an assessment, No. 18, of 6 cents per share, was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, Room 11, No. 303 California Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 4th day of August, 1890, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 25th day of August, 1890, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

A. W. BARROWS, Secretary pro tem.

Office, Room 11, No. 303 California Street, San Francisco, California.

GOVER MINING COMPANY—LOCATION of principal place of business, San Francisco, California. Location of works, near Dutch Flat, Placer county, California.

Notice is hereby given that at a meeting of the Board of Directors held on the 14th day of July, 1890, an assessment (No. 2) of twenty-five cents (25c) per share was levied upon the capital stock of the Corporation, payable immediately to the Secretary, at the office of the Company, 13 and 15 Fremont street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on Wednesday, the 20th day of August, 1890, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on SATURDAY, the 6th day of September, 1890, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

GRAY DEW, Secretary.

Office, 13 and 15 Fremont St., San Francisco, California.

DELINQUENT SALE NOTICE.

CARMELO LAND AND COAL COMPANY, Location of principal place of business, San Francisco, California; location of works, Monterey county, California.

Notice—There are delinquent upon the following described stock, on account of Assessment (No. 1) levied on the Fourth day of June, 1890, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Cert.	No. Shares.	Amt.
O'Connell, Annie A.	18	100	$50 00
" "	19	100	50 00
" "	20	50	25 00
Green, Wm D.	26	150	75 00
Eddy, Ida I.	15	100	50 00

And in accordance with law, and an order of the Board of Directors, made on the Fourth day of June, 1890, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the Company, Room 10, No. 415 Montgomery street, San Francisco, California, on SATURDAY, the Ninth (9th) day of August, 1890, at the hour of one o'clock P. M., of said day, to pay said Delinquent Assessment thereon, together with costs of advertising and expenses of sale.

W. T. BAGGETT, Secretary.

Office, Room 10, No. 415 Montgomery street, San Francisco, California.

HORACE D. RANLETT,

Ores, Mining, and Commission,

420 Montgomery St., S. F.

Ships under advances to smelting works in Boston New York, Baltimore and Liverpool.

Twenty-one years' experience in Shipping Ores and Managing Mines.

Wanted—A Thoroughly Practical Metallurgist

To superintend a large mill working gold and silver-bearing quartz. Must be a first-class Assayer. State past experience and give references. Address, Superintendent, Box 2517, San Francisco, Cal.

About Obtaining Patents.

Patents are Virtually Contracts

The Patent Law provides that in case a patent, which is the evidence of the contract, is not executed in compliance with the requirements of the law, it may be annulled and rendered void. Hence it is of the greatest importance to every inventor that his patent or contract be skillfully and accurately drafted, in order that it may afford him complete protection for his invention during the life of his patent.

How to Procure a Patent.

To avoid all needless delay, however, and secure patents at the earliest moment practicable, inventors will do well to forward a model, drawing or ketch, with a plain, full and comprehensive description of their invention (stating distinctly what the particular points of improvement are), with $15 as a first instalment of fees. If the improvement appears to us to be novel and patentable, the necessary papers for an application for a patent will be prepared immediately and forwarded to the inventor for his signature. When he receives the application and finds it duly prepared, he will carefully sign and return the same plainly addressed to us, with postal money order or express receipt for our own fee. The case will then be promptly filed by us in the Patent Office, and vigorous by prosecuted to secure the best patent possible. [This course is the most expeditious and satisfactory, as no time is lost in transmitting correspondence relative to the preliminary steps.] When the patent is allowed, the inventor will be duly notified, and on sending the final Government fee of $20 to us, we will order the issue of the patent, and forward the same as soon as it is secured from the Patent Office.

The payments are thus divided and made easy. We make no pretense of doing cheap work, in order to entice custom, nor do we afterward make additional charges to bring the bill up to a fair compensation. We do our work honestly and thoroughly, and we never give up a case so long as there is a chance of obtaining a patent. The Agency charge, including drawings, rarely exceeds $40, and for this we do all we can without appealing the case.

Models and Drawings.

Models are now seldom required by the Commissioner of Patents, and generally only in intricate cases. Perfect drawings of practical working machines are more satisfactory to the Patent Office than the old cumbersome system of storing up an immense bulk of commissioned models.

Drawings or sketches, sufficient to illustrate the invention clearly, with a description that will enable us to make a full set of perfect drawings for the Patent Office, is all that we require. A model will answer our purpose as well, however, in cases where the inventor can more easily furnish it.

Secure a Good Patent.

The value and even the validity of a patent often depends on the character, clearness and sufficiency of its drawings. There are thousands of existing patents in which the improvements are but partially or poorly illustrated in the drawings. When an attempt is made to dispose of such patents, the vagueness and defects of the drawings often prejudice capitalists and manufacturers against the invention, while in reality it may be of great value, and would meet with ready sale had it been skillfully, completely and artistically portrayed. In all cases prepared by us, the drawings are made under our personal supervision, by skilled draftsmen in our constant employ, and every precaution is taken to have the invention fully and clearly shown by different views, so that the improvement will be readily understood by the Examiners in the Patent Office, and comprehended by the public when the patent is granted.

Advantages to Inventors on the Pacific Coast.

The firm of DEWEY & CO. has edited and published the MINING AND SCIENTIFIC PRESS continuously since 1860—a period of 30 years. Few agents, who are still engaged in the business, have had so long-extended practice in patent soliciting. The members of the firm give personal attention to the applications intrusted to their care; and their familiarity with inventions and with local affairs in the Pacific States and Territories enables them to understand the wants of inventors on this coast more readily and thoroughly as we believe, than any other agents in America. Thus there is saved a great deal of the time which ordinarily, when distant agents are employed, is wasted in preliminary writing back and forth.

This happy combination of long business experience together and wide connections has placed our firm in a position unquestionably most fortunate for affording inventors prompt and reliable advice, and the best facilities for securing their full patent rights with safety and dispatch at uniformly reasonable rates.

Every patentee of a worthy invention is guaranteed the gratuitous publication of a clearly stated and correct description of his invention, in one or more of our influential and reliable newspapers, affording just the circulation best calculated to widely inform the class of readers especially interested in the subject of his invention.

Caveats.

A Caveat is a confidential communication made to the Patent Office, and is therefore filed within its secret archives. The privilege secured under a caveat is that it entitles the caveator to receive notice, for a period of one year, of any application for a patent subsequently filed, which is adjudged to be novel and is likely to interfere with the invention described in the caveat, and the caveator is then required to complete his application for a patent within three months from the date of said notice. Caveat papers should be very carefully prepared. Our fee for the service varies from $10 to $20. The Government fee is $10 additional.

To enable us to prepare caveat papers, we require only a sketch and description of the invention.

Rejected Applications.

Inventors who have rejected cases (prepared either by themselves or for them by other agents) and desire to ascertain their prospects of success by further efforts, are invited to avail themselves of our unrivaled facilities for securing favorable results. We have been successful in securing Letters Patent in many previously abandoned cases. Our terms are always reasonable.

Inventors doing business with us will be notified of the state of their application in the Patent Office whenever it is possible for us to furnish such information.

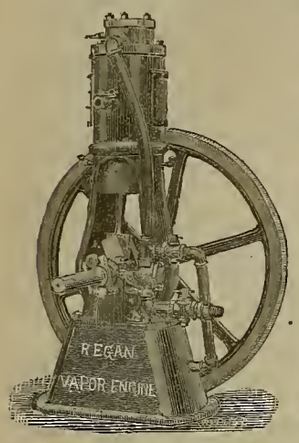
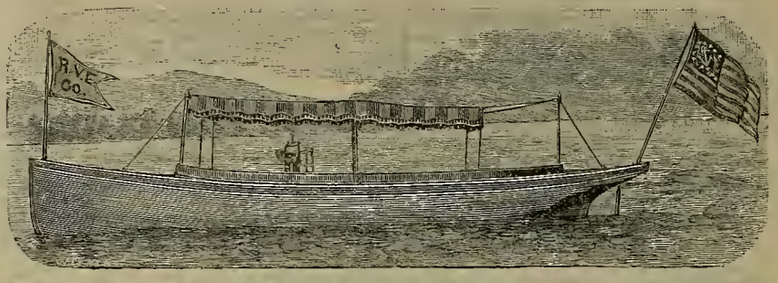
REGAN VAPOR ENGINE.



NO BOILER! NO FIRE! NO STEAM!
Simple, Compact and Cheap.
No Fire or Flame. Started Instantly without Even a Match.
No Ashes! No Explosion! No Engineer!
FULL POWER OBTAINED IMMEDIATELY.
The Moment Engine Ceases to Run, all Expense Stops
NO DANGER.
Horizontal, Upright and Marine Vapor Engines and Launches.
Three fourths to Fifteen Horsepower.
From $175 to $1200.
Send for Our Large Illustrated Catalogue.

GEORGE HAAS, 824 Market St., Phelan Building, } SAN FRANCISCO, Feb. 21, 1890. }

REGAN VAPOR ENGINE CO.—Gentlemen: The 2 H. P. Engine you put up in our factory last November, has given satisfaction beyond my expectations. It does my work better than than those two Electric Motors did, with scarcely any expense for gas. I paid the Motor Company $25 per month for power, while the Vapor Engine has cost me but $2 per month so far. But, be it understood, I have not used the Engine as much as in summer, but the cost of motor would have been all the same, making a saving of $69 in three months. I am satisfied the Engine will pay for itself in less than two years. I use it for freezing cream, run three fans, cocoanut grater, etc.
Yours truly, GEO. HAAS.



Regan Vapor Launches

The uses for small steamboats and launches are innumerable; they are convenient and serviceable for transportation, and are a source of pleasure for those who are fond of sailing. But many have been deterred from purchasing such boats, because of the trouble and inconvenience of using coal, and the necessity of obtaining a Government license, engineer, etc. Our motor does away with these objections. The small space taken up by our engine in the boat **gives more room**; the boat will seat **twice** as many persons as one the same size fitted up with a steam engine. It takes only **two minutes to get under headway**, and can be stopped when running at full speed within the length of the boat, the reverse motion being instantaneous and effective. We carry in stock six regular sizes of hulls, from 18 to 33 feet in length, our models being the best that can be obtained, and built in the strongest and most substantial manner by Thos. Kane & Co., Racine, Wis.

REGAN VAPOR ENGINE CO., 221-223 First St., San Francisco, Cal.

The Pittsburgh Boiler Scale Resolvent.

☞This Resolvent IS NOT AN EXPERIMENT but a FACT, and it will do the work claimed for it at a LESS EXPENSE than any other boiler purge, AND IN NO MANNER INJURE THE IRON.

CARNEGIE BROTHERS & CO., PROPRIETORS OF EDGAR THOMSON STEEL WORKS, } PITTSBURGH, PA. WORKS AT BRADDOCK. Oct. 4, 1887. }

We use the Pittsburgh "Boiler Scale Resolvent," and are well satisfied with the results obtained. We have tested nearly all Compounds presented to us, and this one **is the only good thing we have ever used.** Our feed-water is heated in Berryman Heaters, but owing to distance of heaters from boilers, we rarely exceed 150 degrees of heat in feed-water.

Our water is of the worst character, containing such bad impurities as **sulphate of lime, carbonate of lime, mud, and everything that is bad.** Very truly yours, WM. R. JONES, Gen. Supt.

No water in the United States produces scale in greater quantity or of a harder nature than the Monongahela River, containing SULPHATE and CARBONATE of lime, iron, MAGNESIA, SILICATE, SULPHUR, ALUMINUM, etc. The following well-known manufacturers, who are large steam users IN PITTSBURGH, and using the water from said river as boiler-feed for all their boilers, USE THIS RESOLVENT in their steam plant, and to whom reference is hereby made: Carnegie Brothers & Co., Proprietors of the Edgar Thomson Steel Works; Dilworth, Porter & Co.'s Spike Works; and Oliver and Robert's Wire Co.; and many other firms in the great manufacturing center WHERE THE RESOLVENT IS MADE. Reference is also given to Robert McMahon, Boiler Inspector for Alleghany Co., Penn., and to the following Railway Companies who use it on their locomotives: Kansas City, Fort Scott & Gulf Railroad; Central Iowa; Mexican Central; Delaware, Lackawanna & Western; Burlington, Cedar Rapids & Northern, Terre Haute & Indianapolis; Mexican National; and Denver & Rio Grande Western.

Upon receipt of order, WITH THE PROMISE OF FAITHFULLY CARRYING OUT THE PRINTED DIRECTIONS, we will furnish, FOR FIRST INTRODUCTION, a Barrel, or Half Barrel, of the Resolvent, and the invoice will bear the following stamp:

{ TO BE PAID FOR WHEN RESOLVENT PROVES ENTIRELY SATISFACTORY. }

ALL WORK TESTED AND GUARANTEED.

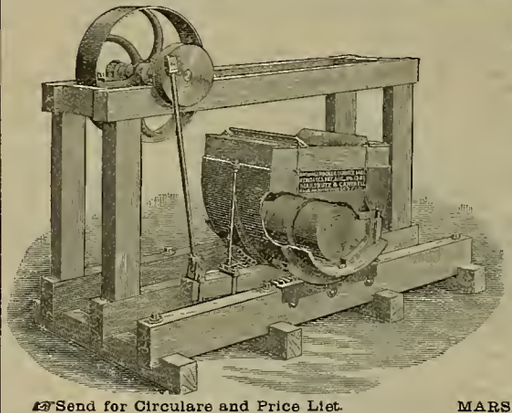
IMPROVED PORTABLE HOISTING ENGINES.

NATIONAL ROCKER QUARTZ MILL.

KENDALL'S PATENT, AUGUST 24, 1886.

CAPACITY. 12 Tons in 24 Hours. 3 H. P.

MARSHUTZ & CANTRELL, Sole Manufacturers.



The Patentee and Manufacturers cordially invite miners to critically examine and pass judgment upon this improved system of milling and amalgamating ores in the following particulars:

1. The cost is less than one-half of stamps of same capacity.
2. The freight to mine is less than one-half of stamps.
3. The cost of erecting is less than one-fourth of stamps.
4. The power to drive it is less than one-half of stamps.
5. The wear is less than one-quarter of stamps.
6. There is no wear except on shoes and dies.
7. In point of amalgamation it is superior to any other machine in use.
8. In its simplicity of construction.

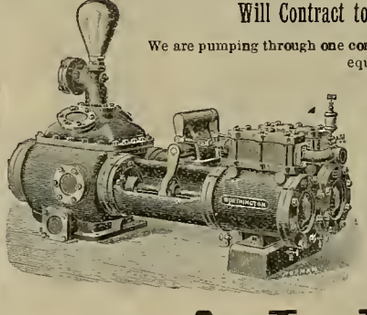
We challenge competition with Stamps, Ball Pulverizers or and other ore crushing machines now before the public.

☞Send for Circulars and Price List. MARSHUTZ & CANTRELL.

WORTHINGTON STEAM PUMPS!

Will Contract to Pump any Elevation at One Lift.

We are pumping through one continuous line of pipe 114 miles long against a pressure equal to 3500 feet elevation.



WE HAVE MORE PUMPING CAPACITY SUPPLYING WATER WORKS
Than all other Manufacturers in the United States Combined.

WE BUILD PUMPS FOR EVERY PURPOSE FOR WHICH PUMPS ARE USED,
And against pressures up to 8000 pounds per square inch.

Send for Illustrated Catalogue.

Free Coach to the House

J. POOLEY.

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, July 24, 1890.

General trade the past week was quiet. Wholesale merchants are receiving goods for the fall trade. With manufacturers a cheerful feeling is reported, as the outlook promises renewed activity this fall.

The money market is fairly easy. Remittances from the interior are free. For moving the cereal crops, the demand for fundsshows a steady increase.

The British steamship Gaelic hence July 19th for China took out the following treasure: Mexican dollars, $147,813; gold coin, $27 374; gold dust, $180; total, $175,367.

MEXICAN DOLLARS—The market has held strong. Since the steamship Gaelic sailed for China, the demand has been light. The market is quotable at 87½@88 cts.

SILVER.—The market held in London at 50d. up to Monday,when the price was advanced to 50¼d., but has since fell back to 50d. The New York market fluctuated more than did the London market. It now begins to look as if speculators abroad and those in this country had exerted their influence to keep silver from being remonetized, for as a commodity the metal is a good gamble. No wonder can be now expressed why London *Money* stated that the Rothschilds and other leading European speculators want to keep silver as a commodity, for it, and all securities whose values are based on that metal's market price, can be made to fluctuate to a much better advantage. The advance in silver in this country and England has caused a corresponding advance in Germany. Russia's silver rouble has advanced to proportionately higher figures than has silver. This advance is due to a demand for roubles to pay for Russian wheat. The advance in the price of silver in Germany is convincing evidence that the price abroad will keep pace with the advance in this country. The local market has held steady at $1.09½, Mint price. Considerable quantities were placed at that figure.

QUICKSILVER.—Receipts the past week aggregate 176 flasks. The market has held fairly firm under a moderate demand and fairly liberal supplies.

BORAX—Exports by sea the past week aggregate 400 lbs. to Victoria. In last month there was sent East by railroad 16,396 centals. The market is steady at current quotations.

LIME—Receipts the past week aggregate 3982 bbls. The local consumption is only fair, while the shipping demand is light.

LEAD—The market is easy but no lower. Eastern mail advices report an unsettled market. There is an impression at the East that silver-lead ores, which are reported to have been stacked up pending silver legislation, will be worked soon.

TIN—The market for spot is dull but no lower. English advices report an active demand for plate on California orders. The East reports a more bearisb feeling.

COPPER—There was shipped in last month by overland railroad 235 centals of copper cement. The market is very strong with still higher figures looked for. The statistical position (see remarks given in the editorial department) of the metal is in favor of the holding interests.

IRON—Imports the past week aggregate ten tons from Oregon. The market for spot, to arrive and shipment is in sellers' favor. English advices indicate better prices soon. Eastern advices report the markets dull but fairly steady. Nearly all the Southern furnaces were blown in owing to hot weather, but they will go into blast with cooler weather. In some parts of the South labor trouble, and at other places a lack of ore and coke is being felt.

COKE—Imports the past week aggregate 100 tons from London. The market is easy.

COAL—Imports the past week aggregate as follows: Seattle, 1200 tons; Tacoma, 780; Nanaimo, 4446; Departure Bay, 2050; Coos Bay, 1100; Comox, 2350; total, 11,926 tons. The market is very strong for all positions. There is a difference in opinion regarding the outlook, but the majority of dealers are inclined to the opinion that higher prices are altogether probable when the winter demand sets in. The list of vessels on the way from and to load at Australian ports is gradually growing.

Mining Share Market.

The mining share market held strong up to Saturday, when, under bear points and systematic cross orders, it began to set off resulting in a 10 per cent cut in prices after 2:30 session on Monday. This was followed by a slight reaction on Tuesday, at the 9:30 session, but after the Call another decline set in, Ophir, Con. Virginia and other North End stocks suffering the most. At the close of the informal session the market looked as if it was going all to pieces, which caused many to sell in expectation of another decline. At the 2:30 session, the market opened with Ophir scoring an advance of 20 per cent; this caused the neighboring stocks to appreciate in sympathy. This hull movement came unexpectedly, for there were no signs of it at the early informal session in the Pacific Stock Exchange. The jump, of course, was one of those mysterious movements which indicate more shorts on the market than ore in the mine, or at least, more than the management is likely to show up. The Gold Hill stocks have been dull and heavy. The delaying of the starting of the pumps and little doubt of more assessments soon are the unfavorable influences at work on Crown Point, Yellow Jacket, Overman, Challenge and other mines at that end. In the outside stocks trading has been light. The present impression on the street is that there will be nothing much in the Comstocks until about September, and some say not until October, when quite a bull move can he expected. In the meantime there will be ups and downs, or a good trading market.

The mining share market opened this (Thursday) morning dull but steady. After regular Call, Ophir and the other North End stocks made quite an upward movement, but the Middles shaded off, while the Gold Hill were barely steady. It looks very much as if the market is fluctuating to higher figures so the pool can unload at a good profit; for during the late depression the outside were free sellers.

From the Comstock mines our advices could not be of a more encouraging character. Active prospecting work is going on in all the mines, but particularly in the Middle and Gold Hill groups. With so much active work it would be singular if valuable strikes of ore in one or more of the mines is not made much within the next 30 days. Ophir has several hundred tons of rich ore in the ore houses; and, it is claimed that the management can take out more ore as soon as desired. The work going on in this mine, Con. Virginia, Mexican, Sierra Nevada, Union and Utah deserves close watching. In Best & Belcher they ought to be nearing the ore lying to the southwest, near the Con. Virginia line. In Savage active work is being done to develop the late find in the 1300 north drift. The shaft is being repaired and sunk to that level, while a winze is being sunk in ore to the 1400-foot level, where drifts and crosscuts will be run. In Hale & Norcross more active prospecting work is under way. The company has laid off about 50 men pending repairs to the shaft. Official advices report that the Potosi 1030 south drift is being pushed ahead in good ore. In Exchequer, Alpha, Con. Imperial, Challenge, Confidence and Yellow Jacket active work is still the order. From Crown Point official advices report the 300 south stope narrowing but the 300 east stope is widening. The battery assays are $3 a ton higher, while Belcher's battery assays are $11 higher. Active prospecting work is being done in the mine. In Seg. Belcher they have taken up the Belcher south drift, which at last advices was in vein material.

From the outside mines continued good reports come to hand from the Tuscaroras and Quijotoas. The Mount Diablo mine reports are of the most favorable character; the battery assays are over $43 a ton, and tailings over $5 a ton.

Reliable private advices received to-day from Virginia report a decided improvement in both Savage and Potosi.

Meetings and Elections.

TUSCARORA M. CO., July 18. Directors—W. R. Townsend, J. F. Holling, Wm. M. Bunker, J. J. Scoville and F. E. Birge. W. R. Townsend was appointed president, J. F. Holling vice-president and J. J. Scoville secretary. The company has an indebtedness of $1466.99.

SAVAGE M. Co., July 18. Directors—H. M. Levy, president; A. K. P. Harmon, vice-president; E. B. Holmes, H. Zadig and Morris Hoeflich. E. B. Holmes continues as secretary and R. P. Keating superintendent. The financial statement, submitted by Secretary Holmes, showed the bullion receipts during the year to have been $232 854 77, and the present indebtedness of the company to be $14,416.89.

YELLOW JACKET M. Co., July 21. Trustees—W. E. Sharon, G. A. Morgan, P. Ennis, G. D. Edwards and J. W. Eckley. J. W. Eckley, president; G. D. Edwards, vice-president; R. F. Morrow, treasurer; W. H. Blauvat, secretary; James Newlands, transfer secretary in San Francisco, and W. E. Sharon superintendent.

Total Gold Product of California.

From the best authorities the following statement of the gold product of California is compiled:

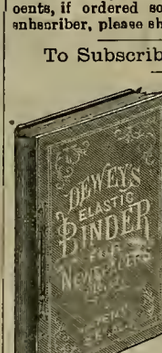
Year.	Amount	Year.	Amount.
1848	$245,301	1870	17,458,133
1849	10,151,360	1871	17,477 885
1850	41 273,106	1872	15,482,194
1851	75,038,232	1873	15,019,210
1852	81,294,700	1874	17 264,886
1853	67,613 487	1875	16,876,009
1854	69,433,931	1876	15,610 723
1855	55,485,305	1877	16,501,268
1856	57,509,411	1878	18 839 141
1857	43,628,172	1879	19,626,654
1858	46 591,140	1880	20,030 791
1850	45,846,599	1881	19,223,195
1860	44,095,163	1882	17,146,416
1861	41,884 995	18 3	17,257 873
1862	38,854,068	1884	13,600 000
1863	23,501,736	1885	11,750,490
1804	24 071,423	1886	14,725,0 00
1805	17 930,853	1887	13,588,614
1800	17,123,867	1888	9,160,087
1867	18 205 452	1889	9,390,044
1868	17,555 867		
1869	18,229,044	Total	$1,172,551,396

This statement is for gold alone, the value of silver, lead, copper, quicksilver and other mineral products not being considered in the table. Notwithstanding the decrease of late, largely due to the suppression of hydraulic mining, California still holds first position among all the States as a producer of gold.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the manse it faithfully serves. Subscription rate, $3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

To Subscribers and Readers.



A HANDY PAPER BINDER—A. T. Dewey's patent elastic binder, for periodicals, music and other printed sheets, is the bandiest, and very cheapest of all economical and practical file binders. Newspapers are quickly placed in it (as received) and held neatly, as in a cloth-bound book. It is durable, and so simple a child can use it. Price (size of this paper, Harper's Weekly, and Scientific American), 75 cents; postage 10 cents. Postpaid to purchasers of this paper, 50 cents. For sale at this office. Send for illustrated circular. Agents wanted.

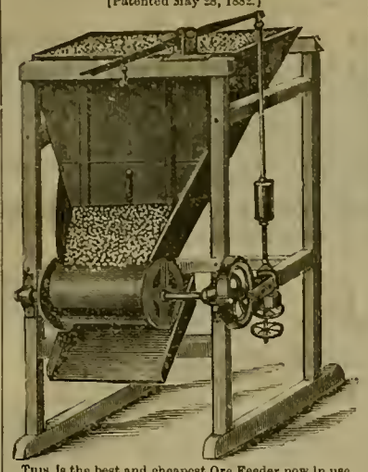
THE ROLLER ORE FEEDER
[Patented May 28, 1882.]



This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.
In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

"HENDY" IMPROVED "CHALLENGE" ORE FEEDER
The best form of Feeder ever devised, and pronounced by reputable mining men to be far superior to any form of "Roller" Feeder manufactured. We refer to the following gentlemen who have furnished us with testimonial letters to the above effect, which can be seen at our office, viz.:
N. W. CROCKER, Supt. Bunker Hill Gold Mining Co., Amador City, Cal.
W. G. ROBERTS, Greenwood, El Dorado Co., Cal.
D. C. WICKHAM, Taylor Mine, Greenwood, Cal.
J. R. TREGLOAN, Supt. South Spring Hill Gold Mining Co., Amador City, Cal.
WE ARE MANUFACTURERS OF THE
"CHALLENGE," STANFORD," "TULLOCK," & "ROLLER" FEEDERS,
And will furnish descriptive Catalogues and quote prices upon application.

Day's Improved Quartz Stamp Mill.
This Mill is designed for the Prospector, the Assayer and Sampler of Gold and Silver-bearing rock. It is a perfect mill, built entirely of metals, and of the best mechanical construction; will amalgamate perfectly in the battery or on plates. It strikes a sharp, heavy blow with a light stamp. Shipping weight, 225 lbs. Price $75. Address
JAMES DAY,
ATLAS IRON WORKS, Cor. Napa and Louisiana Streets, Potrero, SAN FRANCISCO, CAL.
N. B.—CHAPPAREL, Butte Co., Cal., Nov 10, 1889.—Mr Jas. Day, Chico: The little mill is a daisy; it comes up to all expectations; it works perfect in all respects. Yours truly,
WALKER, REESE & Co.

HENRY CAREY BAIRD & CO.,

INDUSTRIAL PUBLISHERS, BOOKSELLERS AND IMPORTERS,

810 Walnut St., Philadelphia, Pa., U. S. A.

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

TUSTIN'S PULVERIZER.

—MANUFACTURERS OF—

MARINE ENGINES AND BOILERS.—Propeller Engines, either High Pressure or Compound, Stern or Side-wheel Engines.

MINING MACHINERY.—Hoisting Engines and Works, Cages, Ore Buckets, Ore Cars, Pumping Engines and Pumps, Water Buckets, Pump Columns, Air Compressors, Air Receivers, Air Pipes.

MILL MACHINERY.—Batteries for Dry or Wet Crushing, Amalgamating Pans, Settlers, Furnaces, Retorts, Concentrators, Ore Feeders, Rock Breakers, Furnaces for Reducing Ores, Water Jackets, etc.

MISCELLANEOUS MACHINERY.—Flour Mill Machinery, Saw Mill Engines and Boilers, Dredging Machinery, Powder Mill Machinery, Water Wheels.

Tustin's Pulverizer

WORKS ORE WET OR DRY.

ENGINES AND BOILERS

OF ALL KINDS,

Either for use on Steamboats or for use on Land.

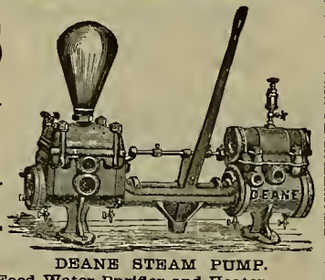
Water Pipe, Pump or Air Columns, Fish Tanks for Salmon Canneries

OF EVERY DESCRIPTION.

Boiler Repairs Promptly attended to and at very moderate rates.

AGENTS FOR THE PACIFIC COAST FOR THE

Deane Steam Pump.



DEANE STEAM PUMP.

SPECIALTIES:

Corliss Engines and Tustin Ore Pulverizers.

Agents and Manufacturers of the Llewellyn Feed Water Purifier and Heater.

THE GIANT POWDER COMPANY

Manufactures Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as

The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,

Of Different Strengths as Required.

NOBEL'S EXPLOSIVE GELATINE," which contains 94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite and even Safer in Handling.

JUDSON POWDER IMPROVED.

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

BANDMANN, NIELSEN & CO.,

CAPS and FUSE for Sale. GENERAL AGENTS, SAN FRANCISCO CAL.

QUARTZ SCREENS

A specialty. Round, slot or punched slot holes. Genuine Russia Iron, Homogeneous Steel, Cast Steel or American planished Iron.

Zinc, Copper or Brass Screens for all purposes. California Perforating Screen Co., 145 & 147 Beale St., S. F.

COAL MINES OF THE WESTERN COAST.

A few copies of this work, the only one ever published treating of Pacific Coast Coal Mining, have been obtained, and are for sale at this office for $2.50 per copy. It was written by W. A. Goodyear, Mining and Civil Engineer, formerly of the California State Geological Survey.

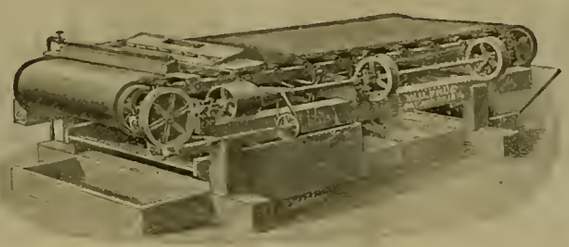
IMPROVED BELT FRUE ORE CONCENTRATOR.

The Best Ore Concentrator in the market, having double the Capacity and doing its work as close as the plain Belt machine, while its concentrations are clean. It is used in a number of Mills, the most notable of which is the Alaska M. & M. Co's Mill, where 24 Improved Belt Frues are taking the Pulp from 120 Stamps, crushing 350 tons per day, and is giving entire satisfaction as against 48 plain Belt Machines, taking the Pulp from the other 120 Stamps.



Protected by Patents December 22, 1874; September 2, 1879; April 27, 1880; March 22, 1881; February 20, 1883; September 18, 1883; July 24, 1888. Patents applied for.

Price of Improved Belt Frue Vanner, $825, f. o. b.
Price of Plain Belt Frue Vanner, $575, f. o. b.

There are Over 2200 Plain Belt Machines now in Use.

THE MONTANA COMPANY (Limited), LONDON, October 8, 1885.
DEAR SIRS:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Yours truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction that 44 additional Frues and more stamps have been purchased. ADAMS & CARTER.

For Pamphlets, Testimonials and further information apply at office.

ADAMS & CARTER, Agents FRUE VANNING MACHINE CO., Room 15, No. 132 Market Street, San Francisco, Cal.

"TRIUMPH" ORE CONCENTRATOR WITH IMPROVED RIFFLED BELT.

The competitive trials which have been held between the "Trinmph" Ore Concentrators, the "Frue" Vanners and other forms of concentrating devices, do not warrant the assertion that the "Frue' Vanner is the best ore concentrator in the market. The fact that the "Frues" have improved (corrugated) belts does not militate against the superiority of the "Triumphs;" for, when desired, they (the "Triumphs") can be mounted with a superior belt known as the "Blasdel" Riffled.

—o—

Price "Triumph" Concentrators, with Improved (Patented) Belt - - - - $650 f. o. b.
Price "Triumph" Concentrators, with Plain Belt - - - - - - - - $550 f. o. b.

—o—

We are prepared to guarantee the superiority of the "Triumph" over the "Frue" or any other form of Concentrator, for coin if need be.
Circulars and testimonial letters furnished on application.

Location of Works, Grass Valley, Nevada Co., Cal.

GRASS VALLEY, NEVADA CO., CAL., Nov. 10, 1886.

Joshua Hendy Machine Works, 39 to 51 Fremont St., S. F., Cal.:

GENTLEMEN—I am pleased to state, in reference to the "Triumph" Ore Concentrators, that four (4) of them were placed in the mill of the Original Empire Mill and Mining Company in April, 1884, and a thorough test made of their practical operation; and their efficiency having been demonstrated, four (4) more were subsequently introduced as the complement of the Twenty (20) Stamp Mill, and the eight (8) have been and are now running with entirely satisfactory results.

At the Ten (10) Stamp Mill of the North Star Mining Company, under my supervision four (4) are also in successful operation, and from my observation of their practical workings, I am convinced that this form of Concentrators is the equal, if not superior to any other style of Vanners or concentrating devices.

DAVID McKAY, Jr.,
[Signed] Sup't North Star and Original Empire Mining Co.

N. B. When the stamping capacity of the two above named mills was increased, more "Triumph" Concentrators were purchased, and twenty-eight (28) are now in constant successful operation.

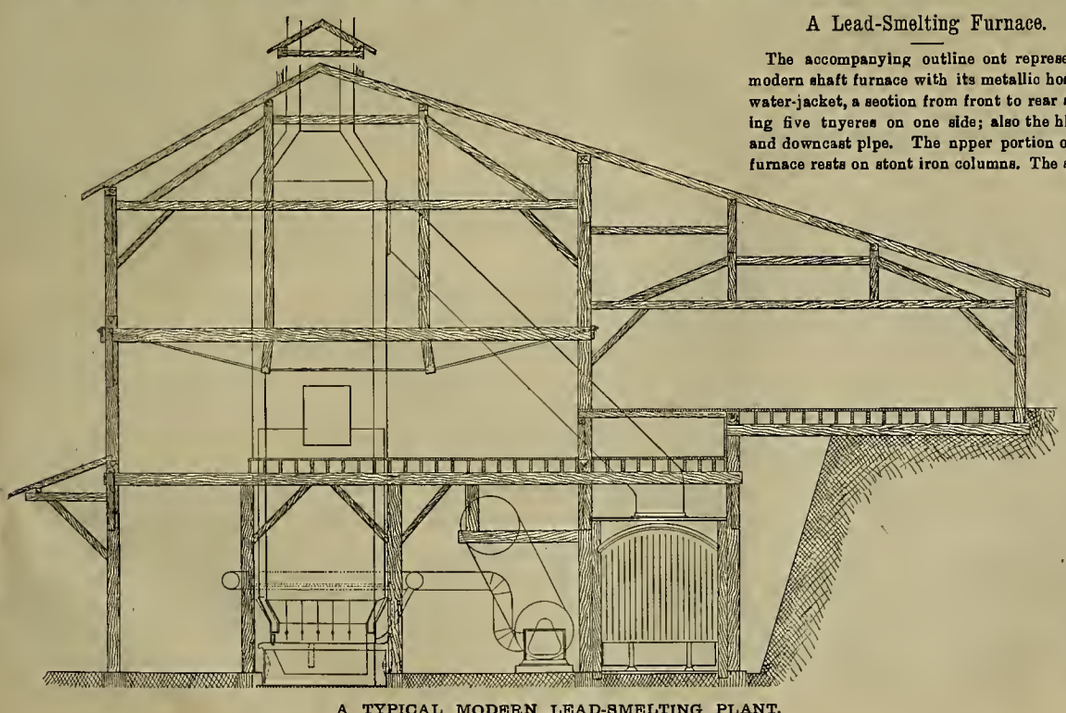
SEA CLIFFS AND TERRACES CAUSED BY THE WAVES OF LAKE BONNEVILLE, ON THE NORTH END OF THE OQUIRRH RANGE, UTAH.—See page 74.

A Lead-Smelting Furnace.

The accompanying outline ont represents a modern shaft furnace with its metallic hosh, or water-jacket, a seotion from front to rear showing five tnyeres on one side; also the hlower and downcast plpe. The npper portion of the furnace rests on stont iron columns. The skeleton hnilding surrounding it is also shown. The ont is one from the report of the State Mineralogist. This fnrnace has a hearth area of three feet six hy eight feet six, and 11 tnyeres, five on each of the long sides and one in the hack wall. The nozzles of the tnyeres are four lnches in diameter. The hight of the fnrnace from the oenter of the tnyeres to the feed-door is 13 feet; depth of the cnoihle helow the edge of the hearth-plate, 26 inches. In this drawing, the hlower (whioh is a Baker, size seven and one-half) is represented immediately in the rear of the fnrnace. It is hetter, however, to plsce the hlower or hlowers, as many as may he required, in the engine-room, not in the fnrnace-room proper. When the hlower is so plnced, it is desirahle that the snpply of air for the hlast shonld he drawn throngh a hrick oondnit oonnecting with the outer air, hecanse if such he not done, the revolutions of the hlower cause a disagreeahle vihration of air in the engine-room, and mnch olattering of windows and other light materials.

If there he more than one fnrnace, it is preferahle to connect as many hlowers as may he reqnired with a general supply-pipe, and draw from it the amonnt of air reqnired for eaoh fnrnace. The main snpply-pipe should have an end valve and safety valves at the proper distanoes. A No. 7½ Baker hlower reqnires 35-horse power to drive it. It will he observed from this drawing that the fine descends to the dnst-chambers from a point in the stack above the oharging doors.



A TYPICAL MODERN LEAD-SMELTING PLANT.

CORRESPONDENCE.

We admit, unindorsed, opinions of correspondents.—EDS.

The Gold Belt of Northern California.

Ancient River Channels and Gravel Deposits.

NUMBER VIII.

[Written for the MINING AND SCIENTIFIC PRESS by JAMES F. TALBOTT, Blue Canyon, Placer Co.]

There was no trace of blue gravel in our claim at Indiana Hill in the outlet channel, but on going back into the hill several hundred feet it set in, first in small patches of fine gravel, then a thin stratum of the same, a few inches thick, covering the bedrock and filling up the crevices. This gradually increases in thickness as you go back, till the whole basin is filled to a depth of from 50 to 100 feet, the bottom generally being the hardest kind of blue cement, probably formed by a combination of minerals derived from the serpentine. The top is very compact, but not cemented; it has the same peculiar blue color, but appears to be wanting in the mineral substances that form the hard cement of the bottom. As the Dutch Flat portion is approached, the bowlders and coarser material take the place of the finer gravel. When the Polar Star claim is reached, we find a mass of rough angular *serpentine* bowlders intermixed with gravel-quartz bowlders and all kinds of material found in this section of country, the whole mass being tinged with that peculiar blue.

Deposits Above the Serpentine.

In the channels and gravel deposits above the serpentine, at Sunny South, Damascus, Red Point, on the Middle Fork Divide, and Shady Run, Lost Camp, Omega and Diamond Creek on the North Fork Divide (Michigan Bluff on the former and Lowell Hill on the latter, right on the eastern border, might be included), none of this peculiar blue cemented gravel has ever been found. It must be obvious from these facts that the world-renowned "Great Blue Lead" originates in and from the great Serpentine belt formation. The conditions observed here in regard to this "blue lead" will apply to any other locality all the same. As the general character of all deposits is about the same, differing only in detail from some local influences. The general belief in the universal richness of "the blue lead" has no more foundation in fact than it is a distinct deposit. Many an old miner at this late day thinks if he can "strike blue gravel and the bedrock pitching," he has a "bonanza." We have seen hundreds of tons of this blue gravel with scarcely a color of gold in it. Where, by the action of water, the gold is concentrated in the blue gravel, it is rich, and not otherwise, just the same as any other colored gravel; hence the conclusion is that the existence of a distinct deposit, known as the "big blue lead" is a myth, and the idea of its universal richness a great mistake.

With reference to the theory here advanced, the main ideas to be kept in view are, that there is but one ancient channel and tributaries within a certain defined locality, and, like the present rivers, is independent and separate from any other. Within those bounds all of the gold found in the present rivers, canyons, modern channel and gravel deposits has come directly from the ancient channel in that certain locality, except that which during the floods and flows was broken from quartz ledges and ground to fine dust, and that which was melted into nuggets by the molten lava, as a considerable amount of it has been, we believe. The main flow of lava through that locality indicates approximately the course of the ancient channel.

First Lava Flow.

The first flow of lava into the ancient river system ended the old and commenced the new. The great changes first observed in the order of the new, are the cutting out of the modern channels and forming the gravel deposits from them in the early stages, of which they are supposed to be in a position midway between the ancient and the present rivers. Subsequently the displaced waters from the ancient rivers have cut the present ones down from a level with the gravel deposits to their present beds, several hundred feet below. The process of filling up and cutting out here commenced and continued till the change was complete, a description of which has heretofore been given. In the practical application of this theory, it is found to be in perfect harmony with all of the conditions and natural methods. The most important consideration in regard to any channel or gravel deposit is the conditions for pay.

With reference to the ancient channels, which contained all of the original deposits of gold, there can be no doubt about the pay, as is shown wherever they have been penetrated.

Modern Channels and Deposits.

There are many modern channels and gravel deposits that are rich and have big pay in them, and many others with comparatively nothing of value in them. It is obvious if all of the conditions were the same, all deposits would be alike. In all of those rich channels and deposits that have been developed the conditions are apparently well defined, and in those only developed on the surface they are supposed to be the same, and the natural methods of formation and results may be illustrated by the process in a hydraulic mine. First, a cut or opening is made through the outside rim back into the pay deposit; a proper grade is given to retain the gold; a good dump or outlet is important to prevent the tailings from blocking up the work, and with all of these, a long run is essential for a big clean-up. It is observed here that any break or outlet from the ancient channels subsequent to the period when they commenced filling up, is termed a modern channel. A break or opening deep enough to let out a portion of the gold from the original deposit, the right grade to retain it, a free outlet and a period of long duration are the favorable conditions for forming rich modern channels and deposits from them. In some localities these channels may run directly from their source to the outlet into the present rivers, which is probably the case at Michigan Bluff, Bath and other points on the Forest Hill ridge. In other localities a number of those breaks may unite in a common channel and form an extensive deposit, as at Dutch Flat and Gold Run. The extensive deposit at Todd's valley is probably of this character. These latter are more in the form of basins than channels. That the most of those channels and deposits were formed under the favorable conditions, on the southern slope of the Forest Hill ridge, it is only necessary to mention the fact that from many single claims on them, of comparatively small area, from $50,000 to $1,000,000 in gold has been taken out. On the opposite side of the ridge are the deposits at Yankee Jim's and Brushy canyon from breaks to the west. There are no breaks through the high rim on the north towards Shirt-tail canyon, consequently there are no deposits on that side. The deposits at Yankee Jim's and Brushy canyon, but a short distance apart, present a remarkable contrast in regard to richness, and show the importance of an unobstructed outlet. In the former no richer deposit of this character has been found in this portion of the State. Two of the favorable conditions are recognized here, outlet and a long run, both of which appear to be wanting in the latter, which is of little value, the fine gold being intermixed all through too much gravel. With a good outlet and a long run the gold would have been concentrated here the same as at Yankee Jim's. The conditions observed in the Brushy canyon deposit might be compared to that in a hydraulic mine where the water is turned off just after a big cave comes down.

The development made by the Mayflower Company, in this deposit, shows there is 400 feet in depth of light material and top gravel overlying the ancient pay channel here. We can account for this only in one way; that is, the floods have carried the lighter material from the higher grades above; there being no outlet, it has filled in here till the floods were turned off by a lava flow.

The Ridges.

The Forest Hill ridge is so very wide that it is possible parallel channels may run a short distance in some localities in the lower portion. The Iowa Hill ridge is quite narrow in the upper portion. The source of this channel has heretofore been described. Two of the favorable conditions are recognized here, outlet and a period of long duration in the lower portion, especially in the deposits and canyons heading in them. It is a well known fact to practical miners, that a big rush in the nature of a slide will carry gold with the gravel and debris a long distance and leave it high above the bedrock, if no water follows to settle and concentrate it; but if a big head of water follows, the heavy coarse gold settles to the bottom first and is concentrated in crevices and spots favorable for retaining it, while the finer gold is carried on below and deposited along, where the conditions are favorable, to the outlet, where it is largely concentrated on the rim by the lighter material being carried away.

We find something of a parallel to this in this channel and its deposits. At Iowa Hill, King's and Wisconsin Hills and Grizzly Flat, the outlets, very rich deposits of fine gold were found on the outside rim; but a short distance above, very rich spots and crevices were found at the head of Indian and Grizzly Canyons, containing principally coarse gold. A few miles up the ridge to the east, is Sucker Flat, where some scattering rich spots of big, coarse gold have been found. Some nuggets worth from $100 to $1000 have been taken out here.

Although there is an extensive body of gravel in the ridge all the way up to Damascus, we have never heard of any rich pay being found in this channel above Sucker Flat. These conditions may be accounted for from the source being narrow and the upper portion of the channel having a steep grade, whereby the floods during the gold-depositing period have swept the greater portion of the gold down into the deposits below. And when the channel commenced filling, the source was blocked up and this body of top gravel from above has filled the upper portion of the channel. Probably the same conditions exist in many of the other modern channels. The upper portion of the channel in the Nevada ridge presents somewhat similar characteristics.

"Modern deposits," as used here, may be termed secondary, to distinguish them from the original deposits in the ancient rivers, and the more recent ones in the present rivers and canyons. Their connection with the latter is apparent and can be more readily demonstrated than with the former. Nevertheless they form the connecting link between the two.

The connection between the secondary deposits and the recent ones in the rivers and canyons can be practically illustrated on the Middle Fork and numerous other places in the gold belt.

Rich Pay in Early Days.

In early days of river mining, some of the richest deposits in the State were found on the Middle Fork. In the summer of 1851 a number of companies united and constructed a continuous flume for several miles on the river, each company having a defined boundary to their claim corresponding with their section of flume. Old-timers who worked on the river that season well remember how some companies took out large fortunes from their claims, while others above and below them "busted up," not taking out enough to pay the heavy expenses incident to such operations in those days, when labor and everything was high.

The results here seemed to establish the prevailing idea that success in mining depended altogether on luck—a primitive idea, ignored by the progressive miner of the period. It was subsequently ascertained that those rich deposits on the bars and in the river were in the immediate vicinity of where a portion of the gold from some rich secondary deposit on the hill had followed the erosion of the present river down to its present level, or where some rich canyon emptied that had cut back into the deposits. It was observed also that those points are mainly on the north side of the river and from the Forest Hill ridge, and that the pay diminishes on going down stream from the richest points.

Immediately below Indiana Hill were rich deposits in the river and on bars of the North Fork, which diminish in richness gradually down to opposite Iowa Hill, where some very rich deposits and bars were found. From a short distance below this last point the richness dwindles down till it becomes very thin.

Devil's canyon was very rich for a distance below from where it cut down from Georgia Hill and connecting deposits about Yankee Jim's.

(To be Continued)

The Oathill Quicksilver Mine.

[From Our Traveling Correspondent.]

This mine is situated eight miles southeast from Middletown, Lake county, California, in some of the finest scenery in America. It is the second in importance and product among quicksilver mines in the United States. The present working force is about 200 men, and the output varies from 200 to 400 flasks per month.

The Shaft

Is a double compartment, and is 900 feet deep, with engines and appliances reminding one of the machinery in Virginia City. They elevate, besides the water, about 60 tons of ore and 40 tons of waste rock daily. The location is upon a steep hillside, and they easily provide for an immense quantity of waste, which indicates many a thousand feet of underground tunnels.

The Furnace.

This was built in 1882, and is an immense affair of brick burned in the locality. The condensers are even more complicated. First comes one of brick, another of iron and a third of brick. Even then the fumes are not allowed to escape, but a spray in the chimney condenses a small percentage even there. It was amusing to notice how carefully the exhaust steam was utilized. After winding a devious way and performing many services, it finally escapes where there is little more to be seen of it than of a man's breath in a cold day.

A New Device for Drying Ore.

As the ore passes from the rock breaker down a sloping bank to the drying pans, it passes through a chamber surrounding a coil of steam pipes. Three inches of rock are above and three below the pipes. This is kept full all the time, and as the ore is shoveled out, it is pretty well dried before it is shoveled upon the regular pans.

A Home Market.

Although the people of Lake county think they are suffering badly from want of railroad communication, they are unusually fortunate in their home market from the mines and springs.

This mine alone has 200 workmen and their families, 30 horses and 18 work cattle to feed. It also requires a large amount of wood and of timber for shafts, tunnels and buildings. It has its own blacksmith and wood-working shops, its butcher shop and store. They consume between 300 and 400 beeves and nearly 2000 hogs per annum. Of course, they use grain, fruit and vegetables in proportion. Now, on the majority of these things, the freight across the mountains operates as a protective tariff. This is only one of the mines. Extensive plants have long been at work at the Bradford and Great Western mines, as well as at Sulphur Bank. Then they are reporting at the Bullion a large ore body that assays $120 per ton.

Mr. B. M. Newcomb, the gentlemanly superintendent at Oathill, has reason to be proud of his home as well as his mine. It is in as sightly a place as an eagle might choose and yet adorned with beautiful trees, garden and lawn, and furnished with the elegance of a city home. A vine maple near the door, that would easily make four cords of wood, is a wonder in its way. They have a school of 23 children up there among the clouds, and a very flourishing Sunday school in which Mrs. Newcomb and her sister take special interest. They had a concert yesterday, and to accommodate their friends had built a beautiful house or bower of evergreens to hold 150 guests. The waterworks lead everywhere and provide an abundant supply of such water as can only be found in the mountains. It is under a 200-pound pressure, that makes fires very insignificant affairs if only they are seen in time. The saw mill is doing very nice work and enough of it to require nine yokes of cattle to supply it with logs. This is one of the mines whose surroundings contain evidences of thrift and attractions of home.

F. S. C.

In Sierra County.

EDITORS PRESS:—Sierra City appears to be getting on very well, considering the very hard winter it has passed through, though it looks a little desolate in the vicinity of the snowslides. There were five slides last winter in different parts of the town. The Sierra Buttes has a large quartz-mill here, but from all appearances it looks as if they were doing very little. I called at the Chips quartz mine, about two miles northeast of Sierra City. They have commenced operations in earnest and employ 25 men fitting up the mill and mine. They use a Kirk and Firth air-compressor and Burleigh and National drills and will soon add another drill. They expect to start the mill in about a month. L. Lock is superintendent of this mine, which is owned by San Francisco parties.

A short distance above this mine, on the Sierra Valley stage road, is the plant of the Sunderhaus Consolidated, formerly the Mountain mine. R. B. Harper is superintendent. They are pushing ahead the work on the big mill for which Robt. Forbes of Downieville is furnishing castings and machinery. The foundry and blacksmith shop are about completed. There is quite an army of carpenters at work framing the mill. The mine is about 6000 feet distant up the mountain and will be connected with the mill by bucket tramway. They expect to have the mill at work by October 1st.

The famous Young America mine, up above Upper Sardine lake, is doing well. They have about 145 men on the pay-roll. They are pushing the No. 4 tunnel ahead which will tap the ledge on a level with the ore-house. There is plenty of good rock in sight for a number of years. P. Dedesheimer is the manager of this property.

J. M. S.

Mining Outlook of Nevada.

The mining outlook of Central and Eastern Nevada is daily improving. Not in the history of the State, excepting in its earliest days, before silver was demonetized, has the outlook for the mines been so healthy as at present, and scarcely a day passes that we do not see in some of our exchanges reports of new strikes and new developments. In Pioche the outlook is very favorable. In Eureka they are extracting and shipping a large quantity of low-grade ore, yielding a profit of about $10 per ton. Tuscarora is prosperous, the mines all doing well. In Humboldt county, from the Paradise mines they are shipping more concentrations, and the mines producing more good ore than they have for years. A rich strike is reported in Winnemucca mountain. At the old camp Unionville, the Arizona mine that produced bullion and shipping ore to the amount of $7,600,000, after lying idle for ten years, was started up again by Sy Wheeler of Booth & Co., Sacramento, and is showing abundance of first-grade ore. The Hope mine or Lucky Dog, as it is known, owned by a Michigan company, have cut within the last ten days five bodies of very rich ore, and so it is all over Middle and Eastern Nevada, and we believe the day is not far distant when Austin will, as in days past, be extracting large quantities of high-grade ore and be making large shipments of bullion. We all know that no mining camp in the State has produced as rich ore as that taken from Lander hill, and it is folly to think there is a person living in Austin in this the nineteenth century, so demented as to believe that the ore bodies have all been worked out, and if the mining population will only have confidence, the town of Austin will, in the near future, put on a new dress and come out with flying colors as of old.—*Reese River Reveille.*

THE CANDELARIA MINES.—The famous Candelaria group of mines in Zacatecas, Mexico, comprise 44 claims and 14 mines. The principal mine of the group is the Candelaria, which was, when the present owners took hold of it in 1873, nothing more than a mere prospect hole called La Mala Noche, a name which was at once changed for that of Candelaria. The first records of its operation are dated June, 1873. All the known veins of the district either border on or pass right through the Candelaria property, and all of them, as well as their off-shoots or spurs, are impregnated with gold and green silver. These metals are especially abundant in the Candelaria vein, in which most work has been done, and which is really remarkable for the quantity of native silver and silver sulphide which it contains. The profits yielded by this property have been remarkable; indeed there are few cases in the history of mining which can bear comparison with the record of the Candelaria mine, and few properties that can boast like it of having given (up to December 31st, 1880) a return of $1,184,959 on an initial investment of $5640.

San Bernardino County.

Its Mineral and Other Resources.

NUMBER IV.

[Written for the Press by JAMES H. CRESMAN.]

Mountain Ranges

After leaving the main Sierra Nevada range at Tehachepi the San Gabriel appears, a high mountain range extending southerly to Los Angeles and Pasadena. Its course is easterly and westerly. Its dominant peak is known as the San Antonio, rising to a hight of 9630 feet above the level of the sea. The San Bernardino range proper, commences where the San Gabriel ends. From this point its strike is south 34 east, and terminating at a point in the vicinity of and opposite Yuma, on the Colorado river. San Bernardino mountains contain several prominent and noted peaks. San Bernardino peak forms the initial point of the U. S. land surveys, at an elevation several hundred feet lower than its summit. San Jacinto peak, situated south of San Gorgonio pass, rises to a hight of 10,920 feet, forming a prominent land-mark, visible from almost any point in the desert region.

Desert Mountains.

That portion of San Bernardino county lying north of the San Bernardino and the San Gabriel ranges of mountains is known as the desert region, which is dotted with short ranges, low buttes and isolated peaks. That mountain known as the Providence range is the most important and of the greatest longitudinal extent. This with Kingston mountain and the Yellow Pine, constitute the principal ranges of this region. Combined, the mountain portion of the desert covers but 5825 square miles of the entire area of 17,476 square miles of mountainous country.

Geology.

The core or axis of the San Bernardino range of mountains is granitic, varying in character and composition from syenite to gneiss and mica schists, with quartzite dykes and lime belts of great width, strength and longitudinal extent. Some of the rocky structure has been highly metamorphosed; hornblendic slates and magnesian rocks also occur. In many places on the northerly slope of the San Bernardino range of mountains unaltered sandstones are seen in immense quantities, particularly in the vicinity of Holcomb valley, in the Bear Creek Hawk, which is a spur of the main range.

On the southerly flank of this range bodies of carbonate are seen dipping at varying angles. On the northerly flank of the San Gabriel and San Bernardino ranges an important belt of limestone occurs of great width and extent. This belt is traceable from San Antonio peak northeasterly through Holcomb valley to Twenty-nine Palms; thence on its line of strike appearing and disappearing as far as the Colorado river, and possibly extending into Arizona. Its width varies from four to ten miles with occasional spots and dykes of syenitic rocks and micaceous schist, trap, porphyries and strata of magnesian and talcose slates. This belt of limestone is not uniform in character. It often changes from a dark-blue mountain limestone to a carbonate of a dazzling whiteness (marble) varying in texture, color and crystalization from that of a yellowish dolomitic magnesian limestone, but still marble. On either the northerly or southerly border of the belt near the contact of granite and mica schist it is invariably metalliferous to a greater or lesser extent, and quite an important figure in the metallic domain of this county. The border metals are, however, as a rule, dissimilar in character. The ores of lead and silver occur at and near the southerly contact, while on the northerly line of demarcation the veins carry gold in paying quantities. The Black Hawk mines are a notable instance of the latter feature. The prospector can here find a virgin field in which to show his skill and test his luck by following the line of contact denoted. This metalliferous belt, both east and west of Cushenbury has been but little prospected. The indefatigable and old-time prospector, O. G. Leach, is the only one that I have ever talked with that seemed to understand the situation.

Silver Mountain

Is an isolated peak or lone butte of insignificant proportion, but of great commercial value as a producer of marble and lime. It lies three-quarters of a mile southwest of the town of Colton. Its dimensions are three-quarters of a mile in length from north to south by half a mile in width, and it reaches an elevation of 700 feet above the level of the sea. We cross the San Bernardino range or Cajon Pass and into

The Desert Region.

The Ord mountain range, inclusive of the Lava Bed range, which is a southeasterly prolongation, has its greatest elevation at 6500 feet in Eagle Peak. It is situated in the Mojave desert, about 50 miles northerly from San Bernardino, and is about 30 miles in length by from four to six miles in width, with a northwesterly and southeasterly strike. The Lava Bed mountain is a prolongation of this range in a southeasterly direction, only divided by a low pass. On its northerly flank the remains of an extinct crater (volcanic rent) are seen with its cup-shape depressions from which at no remote period immense quantities of molten lava were ejected. This mountain range attains its greatest elevation at Eagle Peak, a prominent landmark and feature in the landscape visible from almost any elevated point in the desert region.

This section for many miles, in every direction from Ord mountain, contains almost every known formation, igneous rocks predominating. In the northwesterly extremity of Ord mountain, a massive quartzite dyke appears coursing with the formation and dipping 70 degrees northerly from the vertical. The axis of the range is granite. On either side of the dyke referred to, we found metalliferous veins of quartz of great strength and persistence carrying metallic gold and the ores of copper of unusual richness. The mountain at this point is composed of metamorphic rock, porphyries, granites, magnesian and talcose slates. Eruptive dykes of trap with other varieties of igneous rocks evidence subterranean heat, as previously stated.

The Lava Bed Range

Is a southeasterly prolongation of the Ord. Its course is north 22 degrees east; its dominant peak (Clark's) rises to an elevation of 4500 feet and is located 26 miles easterly from Daggett (in an air line). Its axis is granitic, but so much changed and metamorphosed from the effects of subterranean heat, the evolution of powerful gases and thermal water that it is scarcely recognizable, it being in the immediate vicinity of several prominent volcanic vents which are situated from 4 to 5 miles distant in an easterly direction and has felt their effects. This mountain is traversed by fissures whose strike is 70 degrees west of north. These fissures in the earth's crust have been filled with quartz and a brecciated mass of broken angular fragments of many varieties of rocks which have been ejected by dynamic forces from subterranean depths.

A noticeable feature, however, is that the edges and angles of these fragmentary rocks are sharp and charged, as a rule, with a sufficient quantity of the oxides of iron and manganese (which is disseminated through the mass) to give it a brown black or reddish tinge. Wherever quartz fills the fissure it is invariably found rich, carrying the ores of gold, silver and lead. These vein dykes rise boldly from 10 to 50 feet in hight and form marked features in the landscape which are visible for many miles as their black lines cut the lighter colored formation of the mountain's slope. To all appearances these fissures were at a period anterior to the comparatively recent volcanic disturbance, filled with quartz but subsequently reopened, and their integrity as quartz veins destroyed and shattered by the ejection of a broken mass of the rocky structure through the powerful effects of volcanic action.

Victor Mountain

Is two miles long by one in width, with a northerly and southerly trend. It is 700 feet high, and composed of a close-grained, homogeneous granite, forming the two valuable granite quarries that are being worked in the vicinity of the town of Victor. On the northerly end an extensive lime belt occurs of one mile in width, with an easterly strike, and a longitudinal extent of 12 miles, in which there are veins of quartz carrying the ores of copper, gold, silver and lead. To all appearances, Victor mountain at one time formed the northerly rim of either a river channel, prolongation of the Gulf of California or an extensive lake similar to that of Salt Lake in Utah. Either or all of these theories are tenable and possible. The geological structure of the country goes to prove that many changes have taken place in the topographical features of that portion of the North American continent that lies West of the Rockies. Upheavals and depressions of the earth's crust have repeatedly taken place.

Leaving Cajon Pass, at an elevation of 4676 feet, passing northerly through Hesperia, with her forests of cactus (yucca), we descend into the valley, following nearly on the line of the Mojave river. Victor mountain apparently forms a barrier to the further progress of both train and river, there being no visible outlet. But as we approach the mountain, a narrow gorge is seen barely wide enough to admit our passage, its walls rising sharply to a hight of several hundred feet, through which both river and train enter and pass. We now enter the Mojave desert proper, with its broad acres of barren, sandy, alkaline flats dotted with short ranges and isolated peaks raising their heads above the surrounding plains. A photograph from some elevated point, as for instance from a balloon at a considerable hight, would show a bird's-eye view of what would appear to be an immense sea dotted with numerous islands.

The Oro Grande Mountain,

Whose greatest elevation is 3925 feet, forms the easterly boundary of the Mojave river. It is 10 miles long by 5 in width at its widest point, coursing northerly and southerly. Its stratification is northeast and southwest and largely composed of volcanic eruptive material, porphyry, volcanic debris and a cemented brecciated mass of angular fragments of rock evidently ejected, through which courses dykes of trap porphyry and veins of metalliferous quartz, carrying the ores of gold, silver, lead and copper. These fissures undoubtedly occurred at a period subsequent to the formation of the mountain. On the easterly flank and in the vicinity of the river, a broad belt of nearly pure blue limestone occurs which is extensively used for manufacturing lime. Several kilns are in constant operation in the vicinity of a town bearing the name of the mountain which is situated on the bank of the Mojava river.

Calico Mountain

Is situated 80 miles northerly from San Bernardino. Its highest peak is 2975 feet above the level of the sea. It is 12 miles in length by from 3 to 4 in width. Its strike is north 40 west. The nearest town and railroad connection is seven miles southerly at Daggett. This mountain is known as the Comstock of the desert, from its large output of silver in the past and large reserve in store in the future, rendering it to the capitalistic miner an objective point of great interest for its mineral wealth. To the student and scientist it is an unsealed book, but one of great interest and no less instructive. Its pages have been thrown open and lay exposed to the investigation of the diligent observer and scientific inquirer. Its geological features are simple and easily read. The mountain *per se* consists of an eruptive mass of liparite (porphyritic rhyolite) colored and stained in various hues by the oxides of iron in combination with other minerals. These parti-colored rocks and earth were the origin of its name. There have evidently been a series of eruptions (certainly not less than three) following each other at long intervals—as man understands time—but in very brief periods and in rapid succession, geologically speaking. The first ejected from its deep-seated center the immense beds of tufaceous material that is seen on the surface stained with the various colors of the rainbow decidedly pronounced—from a dazzling white to a jet black; from a cerulean blue to a rosy red, changing to a golden yellow. This strange combination of colors was caused, doubtless, by powerful gases and thermal water that were evolved from cracks and fissures in the earth's crust acting on the metallic contents of the mass. These were the resultant effects of the first volcanic eruption.

Volcanic Periods.

The second of note was not less violent or less destructive. It deposited the enormous masses of brecciated and cemented material, forming a cryolitic paste that covers in places to a considerable depth a large portion of this isolated mountain. Calico mountain was evidently the center of disturbance. Lateral volcanic cones of lesser importance are seen at varying distances of from four to eight miles in the vicinity. This class of volcanoes are known as water volcanoes, ejecting water, mud and broken fragments of rock instead of fire and molten lava. Four miles in a southerly direction in the vicinity of the town of Daggett, a massive outburst has taken place. An oblong hill 250 feet in hight and 1000 feet in length is entirely formed of this volcanic material. At its base we find the Waterloo mill of 60 stamps. At a date contemporaneous with and anterior to this volcanic outburst, that whole country now known as the desert was evidently covered by an inland sea of saline water of considerable depth—in all probability an arm of the Gulf of California. This is evidenced by the saline and alkaline deposits of borax, soda, salt, etc., that are found in each immense quantities in the desert region. A lapse of time occurred and disintegration of the newly formed pasty and rocky structure rapidly ensued, and our newly formed mountain lost its integrity.

Its detritus, through gravity, atmospheric influences and the erosive action of water, sought lower levels. The land encroached on the sea and lakes were formed which, together with the detritus from the surrounding mountains, assisted by the powerful action of the sun evaporated the waters and soon filled the lake beds. The desert became a barren, desolate waste of sand. It must be understood that it was not Calico mountain alone and its vicinity that felt the effect of these forces, but all that territory that lies west of the Colorado river and north of the San Bernardino range of mountains. The zone, belt or line of disturbance took an easterly and westerly course and extended northerly, penetrating the State of Nevada for many miles.

At a Later Epoch

The "fire fiend" again came to the front; he had only been sleeping; his fires had not been extinguished; his strength was renewed and with a fresh accumulation of carbonaceous material he fired up his furnace and turned on steam and Calico mountain once more was in active operation, belching forth torrents and oceans of water with mountains of mud and rock. This powerful and continued blast had its effect. The rocky structure was in a state of fluidity. The furnace was tapped and other vents thrown open from which poured forth a molten mass.

The whole country was in a blaze of fire. Semi fluid lava in immense quantities on descending grades followed low depressions and beds of streams, filling the bede of the few remaining lakes. It was a contest between fire and water, and fire obtained the ascendancy. The east was made and the face of mother earth was covered with a sheet of scoria and lava. The rocky structure in every direction was in a plastic and semi-molten state, sedimentary beds and stratified rocks are seen folded and crumpled into every conceivable shape without a break or flaw.

The westerly flank of Wall St. canyon of the Calico mountain presents a marked illustration of the powerful forces then at work.

Evidently, at a still later period, after a cycle of rest, the fires were again rekindled and again burst forth. At this period the ejected rocky mass was largely composed of felsite, adding another variety of volcanic debris to the already accumulated mass of eruptive matter.

This, apparently, was the third and last attempt of the fire-fiend. We trust that the effects of his last efforts may have sent him to that bourne from whence "no traveler return" and that he may have been cremated in the furnace of his own construction. If so, "peace to his ashes."

(*To be Continued.*)

A Grand Redwood Reservation.

Our readers will be pleased to learn of the progress of Col. J. B. Armstrong's plan to donate a grand area of redwood forest in Sonoma county to the people of California as a perpetual reservation. Col. Armstrong has been a devoted lover of nature always and an earnest advocate of rural improvement which aims to "hold the mirror up to nature," and thus to do away as far as possible with the aspects of the cultivated country, which are almost a desecration of natural beauty. This spirit, of course, manifests itself in many ways, and one feature of its work lies in the effort to reserve certain representative areas of nature's grand work from the ax of the lumberman or settler. This is sometimes accomplished by the Government, sometimes by individual grant, and in some respects at least, the latter method is better, because the grantor being of necessity a nature lover can so place his gift that it shall be beyond the control of those with mercenary motives or those who have no love nor taste for such matters. Government grants or property granted to public use under Government control are very apt to suffer from mismanagement or sacrifice.

Col. Armstrong having prospered in this State of his adoption, now proposes to make a grand gift to the people of California and to place it in such hands that it shall always remain true to nature and true to its beneficent mission. We find in the Santa Rosa *Democrat* an outline of Col. Armstrong's plan, which may not be accurate in all particulars, but it gives outlines of the plan:

"Col. J. B. Armstrong proposes a reservation of a park of 600 acres near the end of the Guerneville branch of the S. F. & N. P. railway, in Big Bottom. Four hundred acres of it are covered with the natural virgin growth of redwood, laurel and other sorts of timber, some of the trees of great size and beauty, from five to 15 feet in diameter, and exceeding 300 feet in hight. It is the last large tract of redwoods on Russian river that is a fair specimen of the great forest once covering its banks in a state of nature.

We understand that it is to be conveyed to trustees, in perpetuity, for the people, under few restrictions, together with an endowment sufficient for the annual income to improve the grounds with drives, ornamental buildings, gateways, porter's lodge, etc. Two hundred acres, being improved with orchards, buildings and the like, are to be made productive so as to yield an annual income toward developing the park, and will afford a suitable site for growing flowers and plants under glass for planting along roadsides and filling vacant places under the direction of a landscape gardener, as time rolls on. For it is not for a day, but for all time. Fifty years hence, when these forests are a memory of the past, the gift will be appreciated. Colonel Armstrong proposes to retain control so long as living, but will begin and complete many improvements, with due regard to preserving the natural features of the forest. One of the restrictions will be a positive prohibition against destroying the timber, or even trimming the trees. The drives and paths will be made throughout so as to bring into view the beauties of the place, and water will be introduced in fountains at various points. The grounds are flanked by the foothills of Mt. Jackson, protecting the big trees from the winds, and there is no reason, except fire, why, with care, the park should not stand for all time."

Such a grand act as the rescuing of such piece of forest land from spoliation and the perpetual devotion of it to public instruction and recreation, should yield the donor much satisfaction in consciousness of well-doing. It will, of course, perpetuate the memory of the donor among men, but that to a man of Col. Armstrong's retiring disposition, is probably the smallest consideration involved. To preserve the trees he loves for the improvement, elevation and enjoyment of mankind, for whose ennobling he has always worked with voice and pen and purse—this is the grand central thought in the project, the realization of which we trust the donor may live many years to direct and enjoy.

SOLD A MINE.—Hans Bender, an indefatigable prospector, has sold an antimony mine in the mountains south of Sacramento canyon to an Eastern company, who will commence shipping ore forthwith. The ore is said to be worth $90 per ton in San Francisco.—*Silver State.*

SAWMILL BURNED.—The steam sawmill belonging to Johnson & Palmer, together with 40,000 feet of clear lumber and about 95,000 feet of rough lumber was totally destroyed by fire last week.—*Adin (Modoc Co.) Argus.*

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SUTTER CREEK. — Amador *Ledger*, July 26: Sinking at the Wildman is progressing. The pump has been lowered to its place, and keeps the water out in good shape. The mill is kept running steadily, and both superintendent and foreman are confident that it can be kept going through the entire sinking.

PLYMOUTH CON. G. M. Co.—Amador *Ledger*, July 26: The superintendent makes the following report: "The drift running south starts in No. 2 level with a crosscut west from the shaft about 130 feet, at which latter point the vein matter is cut, thence it runs south on footwall 1010 feet to end of drift. Seven hundred feet south from where the vein matter is cut by crosscut from the shaft, crosscut No. 1 east was started, which, to a distance 112 feet from the main drift, cut a ledge which is five feet thick in the bottom of the drift, and seven feet in top. On this vein they run north 25 feet, which appears to be the north end of the ore chute. They have run south on ore 50 feet. At this point the vein is five feet thick, the ore is good, and will mill from $10 to $12 per ton. Ten feet north of this point there was a break in the vein, and apparently it was the end of the quartz, but by breaking in east it is found that the ore continues. Three hundred feet south of crosscut No. 1, crosscut No. 2 was started, which was run east 183 feet when it cut ore that is two feet thick in the bottom of the drift and three and one-half feet in the top. The ore at this point will mill from $5 to $6 per ton—so it is, without douht, an ore chute 300 feet or more in length, of an average width of probably five or six feet, which, I think, is safe to calculate will mill $10 per ton. This being entirely new ground, and a long ore chute of good healthy looking quartz, carrying free gold and a fair per cent of iron, it will no douht extend up nearly to the surface, and, as it appears, will increase in width very much as it goes up, and will probably extend down several hundred feet. It must be an extensive body of ore. It looks now as though the old mine had taken a new lease of life, with a good prospect of many future dividends."

MISCELLANEOUS. — Mayne Warren, a mining expert of S. F., is superintending operations at the Clinton Peak mine, which has been recently bonded by the managers of the Clinton Con. Co. Operations are confined to running a tunnel to strike the lead. This tunnel is in a distance of 80 feet, with about 80 feet farther to go to reach the ledge.

AT THE AMADOR gold mine things are running along smoothly. The mill is kept going, with from 40 to 50 stamps in motion. The sulphurets, of which the rock turns out considerable quantities, are said to be of high grade—far above the average in fact. At the Hardenburgh or Casco mine at Middle Bar they have not reached the bottom of the shaft yet. They have met with unexpected difficulties.

El Dorado.

SALE OF GRAVEL MINES.—El Dorado *Republican*, July 26: An important sale of gravel mining properties has just been consummated in this city and a company formed to work the old river channel deposits east of the Benfeldt or Rogers mine. The property purchased includes the Shepler ground, the Anderson claim, the toll-house property and Cowan ground, the whole aggregating nearly 200 acres. The purchasers are H. L. Robinson and James Blair of this city and W. P. Stanley of Cleveland, Ohio, the latter, we understand, investing very heavily. Mr. Stanley is interested in the Melton mine at Grizzly Flat and has been in this county at various times looking after that property. Arrangements are being made to open the ground at once, and the first work will be done at a shaft about 300 feet northeast of the toll-house. A small engine will he moved up from the Barnes mine to pump out the water and hoist. The Rogers mine which adjoins this property on the west has recently been showing some very rich gravel.

Inyo.

CERRO GORDO.—Inyo *Index*, July 26: All predictions of the chronic kickers to the contrary, Cerro Gordo will hoom again. Surprising as it may appear, the many efforts which have been made to entangle and discourage the new companies have not stopped the work of development. They have neither driven the companies from the camp or the county, nor have the malcontenis been ahle to prevent the discovery of pay ore. A recent inspection of the Union mine shows a body of fine lead, going about 75 per cent and running high in silver. In the Dunphy & Keefe mine, the shaft is down 50 feet in ore, assays showing 60 per cent lead and 65 ozs. of silver. There are now over 50 men in the camp, and the number will probahly soon be largely increased.

Mariposa.

WHITLOCKS.—Mariposa *Gazette*, July 26: The pump and some other mining machinery at the Whitlock mine belonging to Judge Walker was lately purchased by Ellingham & Grove. Mr. Ellingham will soon have a fine plant at his mine on Whitlocks.

HART.—The Hart mine under the management of the Sebastopol M. Co. are down to the 100-foot level, and commenced drifting last Thursday.

MALONE.—The Malone is now under full headway, under the superintendence of Mr. Koch, Twelve men are employed at the mine, with John Mitchell as foreman.

Nevada.

THE COE MINE.—Grass Valley *Union*, July 26: There is a prospect that the Coe quartz mine may he started up soon by San Francisco parties, who will operate nnder a fifteen months' hond ohtained on the property by Chas. Stocks. It is expected that the money necessary to operate with will be secured by August 1st.

ANOTHER LEVEL.—The Idaho Co. is preparing to sink for another level, which will be No. 18. The present depth of the mine is about 2200 feet on the incline.

THE MENLO PROPERTIES.—Grass Valley *Union*, July 23: The new shaft on the Wisconsin mine has heen sunk to the depth of 140 feet, and with a change into hard ground the ledge is beginning to show up in high-grade ore, which carries handsomely in free gold and sulphurets. There has been quartz in the shaft all the way down, hut it was not very good in appearance nntil the water was reached and the ground became hard, when there was immediate improvement and gold made its appearance. At this point the fissure is five feet between walls, within a vein of 18 inches, and nnderneath on the footwall is a stringer that is rich. From appearances the ore now in sight will run from $40 to $50 per ton, and it is believed that it will prove an extensive body. A station is heing cut out at the present depth (140 feet), and in a short time drifting and stoping will be commenced. Excellent results are anticipated. At the Homeward Bound the main incline is heing sunk helow the 250 level, and the drifts are heing extended hoth north and south on that level. The vein in the drifts is from 2½ to 3 feet in size, and the ore by milling assays goes to $20 per ton. The vein in the shaft also prospects well, and carries plenty of sulphurets. Altogether the Menlo properties are showing well, and are giving every indication of being profitable. Supt. Wiltse feels much encouraged by the developments.

Plumas.

GREEN MOUNTAIN MINE.—Plumas *National*, July 26: We are informed hy those who know the facts that there has been a partial change of ownership in this extensive lot of mining property. Mr. G. P. Cornell has purchased the one-half interest helonging to Mr. Rogers—Messrs. Goodwin & Goodwin still owning the other half. This property has been lying idle for several years, and as is always the case under such circumstances, has become somewhat out of repair. Under this change it is proposed to commence active work to restore the property to its former capacity and productiveness. The improvements upon the property are extensive and of great value, and with a little money and energy the mine may soon be made a source of great profit to its owners and of prosperity to that section of our county. Mr. Cornell will supervise such work as is thought necessary for the present.

Shasta.

NEGOTIATING FOR MINES.—Redding *Free Press*, July 26: It is rumored about town that a hig English syndicate—if not the Sierra Buttes Co. itself—is negotiating for a number of mines on Squaw creek and is in the Old Diggings district. It is said that if this syndicate gets the properties it is after, the mining industry in that neighborhood will receive an impetus never before equaled in Northern California. It is proposed to huild a network of railroads or tramways connecting the ore dumps of the various mines with an immense milling plant situated on the river or creek hank at or near either Copley or Kennet. A system of tramways as proposed would greatly reduce the cost of milling hy doing away with slow transportation and the necessity of a number of small plants, say one on each mine for instance. By concentrating the machinery and power, lower grade ores may be worked with a profit to a better advantage than higher grade with an inferior small plant. If the syndicate ohtains control of the mines now under consideration, as we hope it may, Squaw Creek will hecome the liveliest mining camp in the northern end of the State. Not less than a thousand men would he put to work for this one Co. alone, and the earnings of this hig force would support at least 200 others in various lines of husiness and traffic.

Sierra.

SIERRA CITY.—*Mountain Messenger*, July 26: Once more times are lively here, all the men heing at work in and around the quartz and gravel mines. The Wm. Tell ledge continues very rich, and is thought to be an extension of the Sierra Buttes. The Hughes Bros.' gravel diggings have yielded handsomely this season. The Sierra Buttes Co. employs 11 men, in charge of No. 9 and upper tunnels, mill, flumes and ditches. Colombo Co. runs 10 stamps and employs 15 men. Work is being energetically prosecuted at the Mountain quartz mine. The mill building will be commenced this week. Ditch and flume will be done hy Aug. 15th. Average value of ore is $8 a ton—low estimate. Later developments show a much higher grade of rock. Mill will be capahle of treating 100 to 120 tons a day. Cost of mining, milling and transportation of ore will not exceed $2.50 a ton. The mine is opened to a depth of 700 feet, with at least two years of ore in sight for the 40-stamp mill.

Siskiyou.

QUARTZ AND PLACER.—Yreka *Journal*, July 23: The quartz mill of Coyle & Jacobs will be started up in a few days at Henley, for crushing 100 tons of blue cement like gravel, from the Black Jack Co.'s claim on Cottonwood creek, near that place. If this gravel turns out rich, there is an ahundance of it in the vicinity of Cottonwood creek and Klamath river that can be mined to good advantage. The Quartz Hill M. Co. are now working their claim at Scott Bar hy hydraulic process, hlasting the decomposed quartz so that it can be run into the sluices. The quartz is rotten and crumhles easily hy the force of power and water, except where masses of quartz are held together hy gold which can be picked out hy hand. As soon as the ditch is cleaned out and repaired from the effects of last winter's storms, the company will secure sufficient water-power to start their mill in crushing the solid quartz taken out ready for crushing. The San Jose Ditch Co., at Scott Bar, is also doing good work in taking out considerable gold hy hydraulic process, expecting to realize the hest yield ever known in that claim, between now and winter. Wright and Fletcher and Eastlick Bros., at Oro Fino, have made a cleanup in their hydraulic mines, with very good success for the present season's run, there having been an ahundance of water to ruo the giants much longer than usual. Campbell of Quartz Valley has been running his hydraulic mine this season with the greatest success, in consequence of the good supply of water, which will last prohably five or six weeks longer in supplying his giants, which have been kept in steady operation day and night since commencing work at close of winter storms. The Klamath river miners are now husily engaged in preparing to hoist pay gravel from hedrock, and some of them are already hoisting, having reached the channel in the cuts made.

Trinity.

NEW RIVER.—Trinity *Journal*, July 26: Stephen Sherwood of New River is in town this week. We get the following items concerning the camp from him: The past winter was so severe that it is only recently that the majority of the mines of New River could he worked. Work has been pushed on the Sherwood mine and since the middle of June over $1500 have been taken out. The mine is now leased. Williams & Hennessy have a lease and Miller, Vaughan, Strong and Ellison have leases. The lessees are taking out ore and running the arastra. The prospects for the mine are good. The Ridgeway resumed operations last Monday. The company will run from the tunnel up to the ledge in the bottom of the shaft. After striking the ledge the company will take out ore and crush. They have a fine stamp-mill. Ladd & Clemens are taking out good rock from the Mountain Boomer mine, and are crushing the ore in their stamp-mill. The Mountain Boomer has been one of the steady dividend-paying properties of the camp. G. V. Hely is taking out good ore from his ledge adjoining Sherwood's and is running his mill. Colgrove.is taking out good ore from the Excelsior mine. Work is progressing satisfactorily on the Uncle Sam, owned by Thynge, Bolles, Gulich & Dennis. They have out some good rock and will hegin crushing as soon as they have finished putting the new boiler in their mill. Smith Brooks is running a tunnel on the Mary Blaine mine, and near him Lindsey is working on his ledge. Ladd & Clements are working some men on the Hunter mine. On the New York Ellen the assessment work has been done; probahly that is all that will be done this year. Work is heing done on the hig ledge on Virgin creek. The ledge is from 60 to 70 feet wide and there is an immense body of ore in sight. A working test of the ore went $120 to the ton. However, the whole ledge will not average that. The camp is picking up after the hard winter, and the prospect for good times this summer is promising. There are not so many men in camp as usual, hut a good deal of work is now going on. In Mr. Sherwood's opinion, the prospect of the camp is better than it has been for years.

NEVADA.

Washoe District.

ORE AND BULLION YIELD.—Virginia *Chronicle*, July 26: This week's ore yield of Comstock mines aggregated 7225 tons divided as follows: Consolidated California & Virginia, 2372 tons, assay value $16.10 per ton; Savage, 511 tons, assay value, $21.33 per ton; Hale & Norcross, 1070 tons, assay value, $15.34; Yellow Jacket, 500 tons, assay value, $22.75; Crown Point, 842 tons, assay value, $19.20; Justice, 191 tons. assay value, $31.94; Alta, 360 tons, assay value, $20.50; Overman, 541 tons, assay value, $17.63; Chollar, 506 tons, assay value, $18.68; Belcher, 332 tons, assay value, $30.53. Following was the hullion yield of the ore product from each of the above mines, estimated on the prohability that 80 per cent of the value of hattery sample ore pulp assays was returned: Con. Cal. & Va., $30,500; Savage, $9160; Hale & Norcross, $13,180; Chollar, $7500; Yellow Jacket, $9100; Crown Point, $13,000; Overman, $7660; Alta, $4600; Justice, $4900; Belcher, $8130. Total, $107,780.

SIERRA NEVADA. — On the 630 level at a point 16 feet from the face of the west crosscut, 600 feet from the shaft station, a north drift is advanced 105 feet, continuing in quartz, clay and porphyry showing low assay value.

UNION CON.—On the 1465 level from the north lateral drift, opposite west crosscut No. 4, east crosscut No. 1 is advanced 614 feet. Continuing in porphyry carrying some clay separations.

MEXICAN.—On the 1465 level, east crosscut No. 1, opposite west crosscut No. 5, is advanced 24 feet in a porphyry formation carrying low-grade quartz, most of which appears in the top of the crosscut.

OPHIR.—On the 1300 level, the winze at a point 10 feet southwest of the raise is down 100 feet. The winze continued in low-grade quartz to the depth of 92 feet, at which point ore was cut and is still showing in the winze bottom, where an excavation large enough for another set of timhers, all in ore, has been made.

CON. CAL. & VA.—The 1300 and 1500 levels continue to yield the usual quantity of ore. There has been extracted during the week from all parts of the mine 2128 tons and 1020 pounds of ore. Shipped to the Morgan mill 451 tons and 1670 pounds of ore, and to the Eureka 1676 tons and 1350 pounds, battery sample assays showing an average value of $16.10 per ton (2372 tons milled). Shipped hullion valued at $56,166.14 to the Carson mint.

CROWN POINT.—Shipped during the week 841 tons of ore, showing an average value of $19.20 per ton hy pulp assays. The pay ore in the 300 level east stope is six feet in width, and that in the south stope is growing narrower.

CONFIDENCE & CHALLENGE. — Joint Imperial south lateral drift from west crosscut No. 1, 1000 level, is out 32 feet, face in porphyry. The joint Imperial north lateral drift is out 415 feet.

BELCHER.—Shipped during the week 332 tons of ore showing a value of $30.53 per ton hy hattery samp'e assays, A joint Seg. Belcher winze, near the south line, is down 12 feet below the 1300 level, bottom in low-grade quartz and porphyry.

SEG. BELCHER.—A winze helow the 1300 level, directly under raise No. 1 ahove that level, is down 12 feet.

JUSTICE.—During the week crushed 191 tons of ore showing a value of $31.94 per ton hy hattery sample assays. The winze helow the 622 level is down 145 feet; bottom in low-grade quartz.

ALTA.—The ore output this week was 320 tons, showing an average assay value of $24 per ton hy pulp assays.

OVERMAN.—Shipped 523 tons of ore during the week showing an average value of $17.63 per ton hy hattery sample assays, of which $10.22 was gold.

BEST & BELCHER.—On the 1200 level west crosscut No. 1 is extended 96 feet. Formation, clay and porphyry with some quartz.

GOULD & CURRY.—On the 400 level the northwest drift is extended 219 feet. Formation, soft porphyry.

UTAH.—On the 725 level the south drift is advanced 175 feet. Formation, vein porphyry and clay.

SCORPION.—The southwest drift from the 600 level shaft station is advanced 698 feet and continues in clay and porphyry.

OCCIDENTAL CON.—Continue to extract ore of fair quality from the stopes on the 400 and 450 levels. The crosscut from the bottom of the winze below the 550 level has reached the wall and is stopped. The material passed through was low-grade quartz.

ANDES.—On the 420 level the north drift from west crosscut No. 2 is in 88 feet. Formation, quartz, clay and porphyry giving low assays.

SAVAGE.—Shipped 511 tons of ore showing an average value of $21.33 hy battery sample assays. The 1300 level north drift is in 117 feet and the west side continues in good ore. There are 10 sets of timhers in place following the ore. At a point 40 feet south of the face there are two square sets in ore. A winze is sunk 12 feet at this point, the bottom in good ore. Bullion on hand valued at $20,000.

HALE & NORCROSS.—Shipped 1072 tons of ore during the week showing an average value of $15.34 per ton hy hattery sample assays. Bullion on hand on July account valued at about $28,000. Ore shipments suspended pending repairs to shaft.

WARD COMBINATION SHAFT.—The 1800 level east drift is advanced 415 feet and the west 453. Both continue in porphyry.

CHOLLAR.—Extracted 506 tons of ore, hattery sample assays showing a value of $18.68 per ton. Repairs to the timhering of the 850 level east crosscut No. 2 in progress.

POTOSI.—On the 850 level the south drift from east crosscut No. 4 is heing repaired. The south drift from the 1030 level station of the winze below the 930 level is out 27 feet, the face in quartz and porphyry.

ALPHA.—The 600 level east crosscut No. 2 is in 67 feet from the shaft, face in clay and quartz. The 600 level southwest crosscut is in 95 feet, the face in low-grade quartz.

EXCHEQUER.—The 500 level east crosscut is in 87 feet, the face in porphyry. The 600 level north lateral drift is out 396 feet; face in porphyry and quartz.

CON. NEW YORK.—The 650 level west drift is advanced 420 feet, the face in porphyry. The north drift from the top of the raise ahove the 800 level is out 378 feet, the face in porphyry.

IMPERIAL.—The 750 level west crosscut No. 3 is in 296 feet, the face in porphyry. The 1000 level west crosscut No. 1 is in 184 feet, the face in harreo quartz.

YELLOW JACKET.—Shipped 500 tons of ore showing average assay value of $22 hy hattery sample assays. The 500 level east crosscut No. 1 from the south drift has entered fine quality ore, four feet being exposed yesterday, assays showing a value of $100 per ton.

Delker District.

THREE MINES.—White Pine *News*, July 20: Chris. Delker has been prospecting in the Butte range and brought with him some rich specimens of gold, silver and copper ores. The district which hears his name is situated about ten miles southwest of Sprucemont in Butte Valley, Elko Co. The three principal mines of the district, of which he is owner, are the North Star, Lone Star and Black Jack Logan. The ore goes largely in copper, but also carries free gold and silver. Assays made from the rock give 45 per cent copper and $22 in gold. The mines are easily accessihle hy a good wagon-road.

Osceola District.

THE NEW DITCH.—Cor. White Pine *News*, July 20: The new water ditch is finished and the company is going to erect quartz mills on the waterfalls. Thus outfitted, our district will he unsurpassed for cheap mining and milling of ore. Our free gold helt is six miles long, and the ledges are all large and lay in a kindly quartzite and porphyry formation.

Robinson District.

GOOD LOOKING PROSPECTS.—White Pine *News*, July 20: The Aurora and Mt. Morgan mines in Robinson district, recently honded hy J. B. Williamson from Thomas Rockhill, are showing up fine. In the Aurora a crosscut run 45 feet one way and 35 the other is all in pay ore. Mr. Williamson feels confident that these honded properties will show up sufficient inducements to command the attention of men seeking profitable investment before snow flies.

Taylor District.

BROWN BULL.—White Pioe *News*, July 20: We learn from a gentleman from Taylor that Bro. Simpson has made an important development in the Brown Bull. Boh has stayed with it for five long years and deserves success.

BRITISH COLUMBIA.

BIG STRIKE REPORTED AT FIELD.—Nelson *Miner*, July 16: Reports come from the upper country that 15 men are at work running a tunnel on the Lanark mine and two on the Maple Leaf. The Carihoo Creek M. Co. is also expected to resume work during the month. These properties are all close to Illecilleweat. It is also reported that a great strike has been made in the Monarch mine at Field, and that an option on the mine has been ohtained hy the owners of the Revelstoke smelter. The Monarch was opened up in the fall and winter of 1888, and 1500 tons of ore shipped from it to the smelter at Vancouver, the smelter being huilt on purpose to work its ore. The smelter was a failure, owing to faulty construction and had management, and has since heen sold for scrap-iron. If the Revelstoke smelter people get control of the Monarch and adjoining claims, the smelter will prohably start up within 30 days. It is a complete one in all its appointments.

ARIZONA.

IN THE BRADSHAW MOUNTAINS.—Arizona *Journal-Miner*, July 24: The Rapid Transit mine in the Bradshaw mountains is one of the most promising mining properties in this Territory. It has been opened up systematically for heing worked economically. The Silver King mine on Groom creek continues to improve with development. In cutting out a station at the 130-foot level, a large hody of very high-grade gold sulphurets was struck. Superintendent M. R. Kiley of the Ryland Mining Co. says everything is prosperous in his camp. F. M. Murphy has deeded the Silver Trail and Smith mines, Hassayampa district, and Chalcedony and Jasper mines, Big Bug district, to Diamond Jo Reynolds, for $14,000. J. D. Helm has taken a hond on the Tiger mine and mill in the Bradshaws. A pack train arrived last night from the Bradshaw mountains loaded with ore helonging to S. Mott of

ie Silver Prince mine. W. J. Wright has sold the Good Luck mine, Pine Grove district, to W. C. Ashford. Jacob Smith has sold one-fourth of the Vire Gold mine and mill-site to Jerry Benninghoff, or $1600. Alex. Carlisle has sold one-half of the Grapevine mining claim, Hassayampa district, to Albert Tuttle, for $1000. W. M. Claypool reports good business at the sampling works. A rich strike f gold ore is reported near Iron Springs. Discoverers f the strike are keeping mum until they can get heir locations filed.

TURQUOISE. — Tombstone *Prospector*, July 24: Owing to the condition of the roads ineident to the rainy season the daily shipments of ore from the roperties of this company vibrate from 15 to 20 ons, this being shipped to El Paso. This amount f output could be trebled without taxing the reerve showing in the Silver Bill alone. On the th of the month sinking was resumed on the main Silver Bill shaft. Over 6000 tons of second-grade re grace the dump.

COLORADO.

THE RED OXEN.—Georgetown *Courier*, July 24: Dr. Franklin reports the Red Oxen as improving right along. In the heading of the adit which is now n 305 feet there is a small vein of mineralized uartz which assays from 5 to 6 ounces gold and ounces silver to the ton.

LITTLE ALICE.—The water has been taken out f the Little Alice. Sinking the main shaft by contract is now in process. The shaft is already down 75 feet, and the present contract when finished, vill make its depth 275 feet. Drifting will then be ommenced.

PILOT KNOB.—James Blanton and Larry Butler re developing the Pilot Knob group of mines on Collier mountain, between Chihuahua and Montezuma. A tunnel has been run which has cut three f the group, all of which show more or less ore. Drifting is progressing east and west on the No. 3 rom the tunnel. In the heading of both drifts here is a vein of solid ore ranging from 4 to 6 nches in thickness which mills from 35 to 40 oz. ilver and one-fourth of an ounce gold to the ton nd 50 per cent lead. A carload will be shipped to Denver in about a week.

DAKOTA.

THE SMELTER.—Deadwood *Pioneer*, July 21: The Baby smelter continues in blast, treating, it is said, about 30 tons per day. A prominent mining man o-day visited the works and expressed himself surprised at the size of the plant, and states that Baby s a misnomer—that it at least is a well-developed niss. No one doubts any longer the ability of Prof. Carpenter to smelt these ores. The regular hipment of matte indicates success. A few persons, however, doubt if such a small plant will pay expenses, but that is something no fellow can find out, as the company keeps its business wholly to itself.

CHLORINATION WORKS. — Upon Sunday this plant was closed down and nearly all hands laid off, owing to some unfortunate break in the machinery which will necessitate some delay, as it is necessary to send East for the broken part. This plant has also been in very successful operation, saving, it is said, nearly the entire gold contents of the ore at a cost not exceeding four dollars per ton.

THE PLUMA.—The Pluma Mining Co. has valuable property, consisting of nine claims and fractions, located at the head of the east fork of Gold Run, adjoining the Homestake, Caledonia and Moultor mines. They also own a fine millsite of 11 acres on Whitewood creek, one mile distant from the mine. For the last five months' run on Pluma ore the cleanups aggregated a little over $35,000, the shipment of bullion for last March being $11,000, a magnificent cleanup for a 20-stamp mill.

IDAHO.

LOST RIVER.—Wood River *Times*, July 21: B. C. Willis and Wilkie Duniway are in town from the Lost River region. A revival of interest in the mines of that region promises to give the settlers a home market for everything they can raise. The Big Copper mines at Houston have been sold to a strong company who have already purchased the smelter attached, and are putting men to work. The company intends to keep 40 men steadily employed, and this will cause other properties in the vicinity to be worked. Near Era there are also signs of an early revival of interest in mine operations. It will be remembered that some years ago the Bannack Co. made a miserable failure there and that its $130,000 mill has since lain idle. What this wealthy company failed to do has been done by a company of three or four prospectors whose industry and knowledge of mining was their only capital. They own a claim in the same gulch as the Horn Silver, upon which they have generally put in the winters, working elsewhere in summer to earn money with which to buy their winter supplies. The claim is called the Ella, and it adjoins the Horn Silver on the same vein. By going about 200 feet deeper than the Horn Silver workings they cut the vein and found it over 12 feet in width and carrying such rich ore that a handsome profit has been realized upon several shipments to Blackfoot since spring.

LOWER CALIFORNIA.

THE CUCAPA PLACERS. — *Lower Californian*, July 24: An Indian came in last Saturday from the Cucapa country with 14 ounces of gold-dust for Mr. F. B. de la Pina, one of the concessionaires of the rich mining district in Cucapa mountains, where the gold was found. The Indian also brought a message from Victor Tapia, the manager of the property, who states that the district is proving itself to be very rich, especially in placers, which are very extensive. Twenty-five men are working within the district comprised in the concession, who are under the direction of Mr. Tapia and foreman, Luis Feliz. The latter gentleman is now in Yuma, where he went to secure 25 more men and also to purchase a dry-washing machine, which is said to be capable of washing 25 tons of dirt a day. The Cucapa placers are from one to two feet above bedrock.

ALAMO NOTES. — Two good showers of rain have blessed Alamo the past week. The Prineesa has struck a new streak that pays remarkably well. J. M. Albright's bonanzita in the Montezuma mine continues as depth is attained, and he is making money. The Arabella and Butler mines have started up with a full force. L. B. Howard is personally superintending them. The Alamo Mining Co. is having its adobe offices incased with lumber, and building an elevator and two ore bins. The big boilers have been set in place on the Indio and Ulises, under the direction of machinist McRae. Additional machinery arrived for the Princesa Co. last Sunday. Pedro Lopez has sold his one-fourth interest in the Aurora and Alamo mines, in Alamo, to Messrs. Rhodes and Russell of that camp, for $10,000 cash. The Aurora was one of the very first mines discovered in the camp, and has been steadily making money for its owners ever since. J. M. Gonzalez is part owner of the Aurora.

MONTANA.

ELKHORN BULLION. — Boulder *Age*, July 26: Four bars of Holter bullion came down from Elkhorn the past week for shipment East. Supt. W. C. Jones, of the Mono mine, reports having struck a fine body of good ore in that mine. Wm. Mitchell has sold to the Gladstone Mining Co. for $500 and other valuable considerations, the Mitchell and Highland Chief lodes, half mile south of the town of St. Louis. It is reported that Rod Leggat and John Brannigan of Butte have made a very rich strike of gold ore on a claim of theirs in the Cardwell district, about four miles east of Whitehall. The Pilot, Amazon district, is shipping two carloads of ore a week to the Great Falls smelter, the returns netting $250 to $300 to the car. Next week the water will be turned from the Boulder river into the ditch on the south side of the river and operations will begin on the Taylor placer mine. The Elkhorn Mining Co. the past week shipped two cars of ore to the Great Falls smelter, and two cars are now at the Northern Pacific depot in Boulder awaiting transfer to the Montana Central depot for shipment to the Parrot smelter at Butte. The Lookout mine, Willow Springs district, does not make a satisfactory showing and work will probably be suspended this week, at least temporarily.

FINE SILVER ORE.—*Mining Review*, July 20: Mr. A. P. Dodge, general manager of the Big Ox mines, was up to the upper mines a few days ago and took out some ore from the pay streak that assays $480.90 in silver to the ton. This streak is fully three inches wide, and a foot of the vein will average $139.22. Capt. Jno. Roberts, the mining expert of the Big Ox Co., informs us he can stope out 300 tons of high-grade ore from this shoot alone.

FROM NEIHART. — The bond on the Moulton mine for $50,000 will be taken up to-day by a Great Falls syndicate. The mine is owned by John McAssy. The bond on the Compromise mine for $18,000 was taken up on the 12th inst. by a Great Falls syndicate. A good strike has been made in the tunnel of the Monarch mine. At present two shifts of six men each are being worked, but more men will be put to work about the first of next month.

CASTLE.—Mr. Suydam of Castle was here Monday. He is of the opinion that Castle is the greatest carbooate camp in the world. He thinks the Yellowstone is as good a mine as the Cumberland.

WHITLATCH UNION.—One of the best signs of the times is the iocreased activity manifested all around that famous old-time money-producer, the Whitlatch Union. That the almost abandoned camp was sure to be rehabilitated and Unionville rehuilt was never for one moment douhted by those who best knew the merits of the mines thereabout.

NEW MEXICO.

CAMP LOOMIS.—Cor. *Southwest Sentinel*, July 15: We have a new and prosperous camp in Lone Mountain mining district. After consulting all parties interested in the new strike recently made—which is now owned by Beall & Brockmann—I find they unanimously agree to name the camp in honor of the discoverer, H. W. Loomis. The Good Luck, the name of the new discovery, improves as work progresses, and sufficient has been done to insure a wonderful producer. Other claims are now being developed with most satisfactory results. The Missouri, owned by Bisby, Sweetland & Co., bids fair to develop a bonanza for them. Dan Rose & Bro. will commence work here soon on their Sunset mine. There is considerable interest manifested both here and at Lone Mountain. Some mines are changing hands; more good strikes are being made than is common; new men are coming in and taking leaseholds; old ones are returning.

OREGON.

SPARTA MINES. — Bedrock *Democrat*, July 21: The mines of Sparta, both quartz and placer, are making a very favorable showing this year and are giving proof to the statement that as rich quartz here abounds and as extensive gravel deposits are to be found as in any other district in Eastern Oregon. Between Sparta and Sanger many valuable quartz deposits have been developed this year, in many instances the ore proving wonderfully rich and justifying the expense of the erection of milling plants. At Paddy's Paradise, O. S. Buckland and others have developed a very rich deposit of gold ore and its permanency is assured. The Dr. Marrotte mine is proving a bonanza and a sale of the property to an Eastern syndicate, who will erect a 20-stamp mill upon it, is daily expected. George Henderson, owner of the Del Monte mine, has negotiated with a prominent Union Pacific official for the sale of a one-half interest in consideration of the purchasers erecting a mill on the property. Mr. Henderson is now on his way East for the purpose of purchasing the necessary machinery. The mill which he will select will be of the Griffin patent, with capacity of 50 tons per day. The Eagle canal is furnishing a large supply of water to placer miners this year and a large number of claims are being worked successfully. On Thorn gulch, Capt. E. E. Clough has a large force of miners at work and the ground is said to pay $3 to every square yard. At Shanghai gulch Clough and Graham are mining and the claims are paying fully as well as they did years ago.

UTAH.

THE FLAGSTAFF WORKS.—Salt Lake *Tribune*, July 23: Prof. Vincent is leaving London on an African trip, to return in October. At that time the rebuilding of the Flagstaff works will be decided. In the meantime the ore will be taken out through the Vallejo tunnel, connecting with the 600-foot level of the Flagstaff.

MINERAL WEALTH.—Mr. H. Donovan returned to Salt Lake yesterday from an extended trip down in the southern part of this Territory. He comes back highly elated with some fine specimens, not of gold, silver or lead, but of something that is as scarce and as valuable. He has one large lump of cleorite from the Blackhawk mine weighing about 40 pounds, and cut out of a solid mass from two to five feet in thickness. There is estimated to be 500 tons, and not half the deposit exposed. This has run out of the mountain from two different crevices, and as soon as exposed to the air becomes like wax. The owners of this mine are Mr. Donovan, ex-Sheriff John W. Turner of Provo, Mr. Jas. Bean, Mr. John Dounard and M. Stalter of this city. One other mine of which the same parties are the owners is the Blackbird; it is a jet mine and as bright as any jet ever imported here from England. This is the genuine, and is equal in quality to the English jet, but as that is becoming scarce, they have substituted other compositions. He also brought samples of the ozocerite from the Ozocerite M. Co. mine at Soldier Summit, about six miles west from Pleasant Valley Junction, where the same company has a solid 4-foot vein of this valuable wax or ozocerite and are down only 100 feet.

WASHINGTON.

ON THE COLVILLE RESERVATION. — Spokane Falls *Chronicle*, July 21: It is highly probable that when the great Colville Indian reservation is thrown open to settlement some of the richest mines in the world will be developed. A gentleman was in this city yesterday with a sackful of extremely fine specimens of gold-bearing rock and fine gold. He and a companion took the specimens from undeveloped diggings on the reservation, and as they have exhibited their find to almost every person between here and the Little Dalles, mining men are considerably wrought up, and it is not improbable that ere this other prospectors have gone into the forbidden region. The Little Dalles correspondent of the Colville *Miner* was last week shown the specimens. He is a mining expert, and his opinion that the stuff came from very rich diggings has added unusual interest to the find. The gentleman who had the specimens refused to tell even the approximate location of the rich ground. He purposes remaining in the vicinity of the big reservation, and, when it is thrown open, to locate his claim. He is confident he has a bonanza. For the past two or three years prospectors have been making surreptitious incursions to the heart of the reservation, but very few of them have found anything unusually rich.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING JULY 22, 1890.

432,851.—STUMP-PULLER—S. W. Baker, Olallo, Wash.

432,594.—VARIABLE ECCENTRIC — Dan'l Best, San Leandro. Cal.

432 929.—ROTARY WATER-METER—F. A. Bishop, S. F.

432 863.—STEAM-FOOD COOKER—Olive C. Christin, Brodie, Cal.

432,817.—VENTILATOR—Wm. T. Cottier, Oakland, Cal.

432,696.—WINDMILL—Evert DeWitt, Hanford, Cal.

432,934.—FIRE-KINOLER—Ford & Baird, Placerville, Cal.

432 827 —RAILWAY CATTLE GUARD—James C. Gould, San Jose, Cal.

432 730. — CABLE RAILWAY CONSTRUCTION—Geo. F. Gray, S. F.

432,732.—LIFTING JACK—I. N. Groves, Montesano, Wash.

432,477.—SALVE—W. R. Hall. S. F.

432 528.—RIVETING MACHINE—Harper & Hamlin, Los Angeles, Cal.

432,875.—WATER-WHEEL—C. C. Hogue, Corvallis, Or.

432,799.—BLIND-HOLDER—W. S. Holland, Pasadena, Cal.

432,876.—MIDDLINGS PURIFIER—R. I. Hottel, Cedarville, Cal.

432,670. — CONDUIT ELECTRIC RAILWAY — B. Jennings, San Jose, Cal.

432,944. — CONDUIT ELECTRIC RAILWAY — B. Jennings, San Jose, Cal.

432,831.—PENCIL BOX—H. Legge, S. F.

432,637.—LOADING ELEVATOR—Thos. McConnell, S. F.

432,954.—STREET-RAILWAY CAR — E. C. Sessions, Oakland, Cal.

The following brief list by telegraph for July 29, will appear more complete on receipt of mail advices:

California—Lucius E. Ashley, assignor of one half to A. Clark, Stockton, ditching and grading scraper; Daniel Best, San Leandro, wheel; Arthur H. Douchy, San Diego, valve and faucet; Geo. R. Driggs, San Francisco, water dyeing machine; Geo. Gibbs, assignor of one-half to F. A. Robbins, San Francisco, stock and die for cutting metal screws; John Jett, San Francisco, bicycle; Geo. H. Malter, San Francisco, aging wine; Edwin McDonald, willow washing machine; A. W. Reppy, assignor of one-half to T. C. Masteller, Oakland, automatic electric train signal; Thos. P. Mehwartz, Stockton, combination tool; Adrian R. Smith, San Francisco, feed-water heater and purifier; Dormer Walsh, assignor of one-half to F. H. Manker, San Francisco, game.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

VARIABLE ECCENTRIC.—Daniel Best, San Leandro, Alameda, Co. No. 432,594. Dated July 22, 1890. This is one of that class of eccentric mechanisms in which the eccentric disk is mounted and adapted to be moved upon the shaft to vary its position, and is therefore known by the title of "variable eccentric." The object of the invention is to provide a simple and accurately operating variable eccentric, which is accomplished by certain novel constructions and combinations of mechanism.

CONDUIT ELECTRIC RAILWAY.—Byron Jennings, San Jose. No. 432,944. Dated July 22, 1890. This invention relates to that class of electric railways in which continuous conducting rails are fixed within a conduit or tube, and upon which the wheels of the trolley are adapted to travel, said trolley being connected with the car and the motor thereon, so that a current of electricity conveyed through the rails will pass through the trolley to the motor through which the car is propelled. The object of this invention is to provide a more perfect means of conduction, to allow the conducting rails to expand and contract without interfering with their conductivity, and to provide a perfect conductor through the trolley-wheels and frame, to prevent dirt and foreign substances from falling upon the conducting parts so as to endanger the conductivity or insulation thereof, and to provide means for lubricating the moving parts of the trolley.

CABLE RAILWAY CONSTRUCTION.—Geo. F. Gray, S. F. No. 432,730. Dated July 22, 1890. This patent covers a certain construction of the roadbeds of cable railways. It consists in the novel frames which carry the track-rails and the slot irons, in the braces connecting adjoin-frames with the slot-irons, and in the means for securing the track-rails. The object is to provide simple and effective supporting frames or iron work of the roadbed, which, while being cheap and strong enough to answer all the purposes of such constructions, will permit the use of much less concrete than is generally employed.

LOADING ELEVATOR.—Thos. McConnell, S. F. No. 432,637. Dated July 22, 1890. This invention relates to that class of elevators used for the transportation of goods from one level to another and especially for the use of loading ships. The object of this invention is to provide an elevator of this class which is adapted to be self-supporting and adjustable to any desired inclination, thereby especially adapting it for loading ships.

SALVE.—Walter R. Hall, S. F. No. 432,611. Dated July 22, 1890. This is a medical compound to be used externally as a dressing for wounds, cuts, burns, old sores, salt rheum, eruptions of the skin, etc.

CONDUIT ELECTRIC RAILWAY.—Byron Jennings, San Jose. No. 432,670. Dated July 22, 1890. This device is specially applicable to what is known as the conduit system in which the electrical wires are stretched within a tube or conduit beneath the surface of the ground in such a manner that a trolley-wheel connected with a motor upon a car is allowed to travel in contact with the conducting wire so as to furnish a power to operate the motor. The invention consists in supports to which the conducting wires are fixed; in a means for automatically maintaining the tension upon said wires; and in a compensating device for the expansion and contraction of the wires.

Mining Share Market.

The mining share market has been decidedly mixed, with the leader in one group going up while the leader in another group went down, with another group only showing a slight variation in prices. The movements, so far, have demoralized the street; only those who are "steered" have been able to make successful turns.

Potosi at a break-neck speed broke nearly $3 a share, while Ophir moved up about $2 a share. After touching $5, Potosi began to advance and Ophir to set back after selling at $6. The stocks in each group moved to some extent in sympathy with the leaders. The moves were nothing more nor less than unadulterated manipulation, for the condition of neither the Ophir winze nor the Potosi winze or drift has anything to do with the fluctuations further than giving an excuse for the ups and downs. In all the mines interesting prospecting work is being done.

In outside stocks dealing has been quiet at generally lower prices.

A correspondent wants to know if the 30,000 tons of tailing from the Morgan mill does not belong to the Con. Virginia Mining Co. We are informed that tailings, etc., from the mills belong to the mill ring. This no doubt accounts for the ring being said to be opposed to mine or car sample assays, for they can have more hoodle.

The market opened this (Thursday) morning fairly active at higher prices in the North Ends and lower in the Middles.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, $3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, *or beyond the time he intends to pay for it*, let him not fail to write us *direct* to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

USEFUL INFORMATION.

SUGGESTIONS BY A PHOTOGRAPHER.—A prominent photographer, interviewed recently by a representative of the New York *Sun*, has given a number of valuable hints. This photographer says, what has been said many times, that few people stand before a camera without the expression, "I am having my picture taken," defeating their own object. The second difficulty is that materials having a gloss never produce good effects in a picture; but the majority of women, though they may own any number of dresses that fall in soft, clinging lines, persist in wearing new glossy materials that have not become adjusted to the figure.

There is nearly always the possibility of producing an attractive if not a beautiful picture of a child, if the child is left for direction to the photographer. In reply to the question, "What is the most annoying thing about your work?" the answer was:

"Oh, the fond mothers who insist on dressing children in garments heavy with frills, instead of the soft, fine little dresses that fall in pleasing lines. Then, too, they insist sometimes on having a foot or shoulder, or more often a sash or shoulder knot, show, to confusion of art and the destruction of unities; or they will dart out and twitch a little skirt or mantle that has fallen into natural curves of beauty, or a wandering curl, that falls in exquisitely careless grace, back into order and awkwardness again. That happened the other day when I was photographing a bride. She walked up to the chair, and as she turned to face me, the silk train and thin veil fell in wonderful folds of graceful outline. I told her not to stir, but while I stepped back to get the effect, her friend darted out and straightened the whole thing out like a flag in a head wind."

The same lack of artistic sense that placed the furniture in a room at right angles, still thinks the straight line the line of beauty, curves representing disorder.

ARTIFICIAL HONEY A MYTH.—The seasons of 1887 and 1888, especially the latter, were unpropitious for the "busy little bee," and yielded but little honey. The crop was a general failure, not only in America but also in Europe. The modicum of honey produced, especially of comb-honey, was soon exhausted, and the dealers as well as consumers, North, South, East and West were crying out for honey. The producers were inundated with letters and orders which they could not fill. Now here was the grand opportunity for the manufacturers of "artificial honey." If the article could be sold "at an immense profit at half the price" of the genuine article, as Prof. Wiley assures us, these bogus manufacturers could have coined money—there were "millions in it" apparently. But they failed to appear. The glucose was available, the paraffine ditto, and the "appropriate machinery" ought, in the interval under the law of progress, to have become still more "appropriate" and perfect in its work; but, strange to say, the famine of honey continued. The tempting prices were offered in vain. Not a pound of the stuff ever "materialized," so far as anybody could find out.—*Ex.*

OUR POPULATION.—A telegram from Washington says the census will show that while the rate of increase in the Northern and Atlantic States has been about the same as usual, the Western States have increased at an almost fabulous rate. Of the Southern States, Alabama, Georgia and Texas will show a marvelous increase in population. The other Southern States will remain about the same. It is probable the census will show that the rate of increase among the blacks has fallen far behind the rate of increase of the whites. The Census Bureau is now enumerating the returns at the rate of 1,000,000 per day. As a matter of fact 2,000,000 a day are being counted, because on each day, besides the 1,000,000 new names counted, the 1,000,000 counted the previous day are recounted to insure absolute accuracy. It will take 60 days, and possibly 70, to complete the entire count, which it is reasonable to believe will be concluded about September 1st.

THE INVENTOR OF THE LETTER COPYING-PRESS.—But few people, we presume, are aware of the fact that among the numerous inventions of Watt, was that of the letter copying-press. In addition to the steam engine, with which his name is most intimately associated, Watt's other inventions are too numerous to mention, and most of them—such as the parallel motion, the governor, and the steam engine indicator—are well known to have come from him. But the very multitude of his inventions makes his name to be little associated with some of his most fruitful works. Had he made no other invention, or had he been of a more self-assertive disposition, his name would probably have become known wherever business is conducted, in connection with his invention of the method, still almost universally in use of copying letters by means of the copying-press.

GRASSHOPPER SOAP.—A Spanish inventor renders from grasshoppers a fatty substance which is declared to make the finest soap yet produced.

A NEW METHOD OF OBTAINING STAINED GLASS is done by a process of printing. The design is embossed on an iron plate, on which a lump of hot glass is rolled until it takes the form of the plate on which the pattern is cast. The sunken lines are then filled with enamel and the whole plate is fired. This process obviously does away with the use of leads, is rapid in its execution, and has the additional advantage that the design may be repeated as often as it may be required.

GOOD HEALTH.

The Prevention of Sunstroke.

The following hints for the prevention of sunstroke are given by Dr. Erwin C. Mann of New York city, in an article upon this subject in one of the medical journals: "To avoid sunstroke, exercise in excessively hot weather should be very moderate; the clothing should be thin and loose, and an abundance of cold water should be drunk. Workmen and soldiers should understand that as soon as they cease to perspire, while working or marching in the hot sun, they are in danger of sunstroke, and they should immediately drink water freely and copiously to afford matter for cutaneous transpiration; keep the skin and clothing wet with water. Impending sunstroke may often be warded off by these simple measures. Besides the cessation of perspiration, the pupils are apt to be contracted and there is a frequency of micturition. If there is marked exhaustion with a weak pulse, resulting from the cold water application, we should administer stimulants. The free use of water, however, both externally and internally by those exposed to the direct rays of the sun is the best prophylactic against sunstroke, and laborers and soldiers and others who adopt this measure, washing their hands and faces as well as drinking copiously of water every time they come within reach of it will generally enjoy perfect immunity from sunstroke. Straw hats should be worn, ventilated at the top, and the crown of the hat filled with green leaves or wet sponge. It is better to wear thin flannel shirts in order not to check perspiration. We may expose ourselves for a long time in the hot sun and work or sleep in a heated room and enjoy perfect immunity from sunstroke, if we keep our skin and clothing wet with water."

SEVEN HOURS' SLEEP AT LEAST.—There is not one man or woman in 10,000 who can afford to do without seven or eight hours' sleep. All those stories written about great men and women who slept only about three or four hours a night make very interesting reading, but I tell you, my readers, no man or woman ever yet kept healthy in body and mind for a number of years with less than seven hours' sleep. Americans need more sleep than they are getting. This lack makes them so nervous and the insane asylum so populous. If you can get to bed early then rise early. If you cannot get to bed till late, then rise late. It may be as Christian for one man to rise at 8 as it is for another to get up at 5. I counsel my readers to get up when they are rested. But let the ringing bell be rung at least 30 minutes before your public appearance. Physicians say that a sudden jump out of bed gives irregular motion to the pulse. It takes hours to get over a too sudden rising. Give no time after you call us, to roll over, gaze at the world full in the face, and look before we leap.—*T. De Witt Talmage.*

POISONING BY LEAD DUST.—Cases of lead poisoning among the jacquard weavers in a Swiss factory were traced to the dust from the leaden weights which are used by the weavers to carry the thread of their warp. After the varnish has been rubbed off from the weights, the lead begins to wear away and falls in fine particles among the dust on the floor. In some cases the dust was as much as 56.86 per cent lead, and even when the utmost care had been taken, nine or ten per cent of lead was found in it.

NOSE BLEEDING.—An eminent physician says: "The best remedy for bleeding at the nose is a vigorous motion of the jaws, as if in the act of mastication. In the case of a child, a wad of paper should be placed in its mouth, and the poor child instructed to chew it hard. It is the motion of the jaws that stops the flow of blood." This remedy, he says, is so extremely simple that many will feel inclined to laugh at it; but it has never been known to fail, even in severe cases."

THE GROWTH OF NAILS.—It is said that the growth of nails on the left hand requires eight to ten days more than those on the right. The growth is more rapid in children than in adults, and goes on faster in summer than in winter. It requires an average of 132 days for the renewal of the nails in cold weather, and but 116 in warm weather.

THE TASTE.—Different classes of substances have been found to affect the organs of taste in the following order: Bitters, acids, saline substances, sweets and alkalies. The taste nerves are nearly 2000 times as sensitive to quinine as to sugar.

BOILING MILK.—Experiments in St. Petersburg have shown that boiling milk greatly reduces its nutritiousness.

GOULD, with all his millions, has to walk the streets at night to induce sleep.

ENGINEERING NOTES.

Relative Costs of Transmission of Power.

The following comparisons of cost of transmission of power by various methods appeared in the *Revue Universelle des Mines:*

1. Comparative cost on 10-horse power transmitted 1093 yards: By cables, 1·77 per effective horse-power per hour; by electricity, 2·21; by hydraulics, 2·90; by compressed air, 2·98.

2. Comparative cost on 50-horse power transmitted 1093 yards: By cables, 1·35 per effective horse-power per hour; by hydraulics, 1·87; by electricity, 2·07; by compressed air, 2·29.

3. Comparative cost on 10 effective horse-power transmitted 5465 yards: By electricity, 2·64 per effective horse-power per hour; by compressed air, 4·66; by cables, 4·69; by hydraulics, 5·29.

4. Comparative cost on 50 effective horse-power transmitted 5465 yards: By electricity, 2·37 per effective horse-power per hour; by cables, 2·65; by compressed air, 2·99; by hydraulics, 3·02.

Steam was the prime mover used in each of the above instances, and it appears that for long distances electricity takes the lead in economy over all other systems. It has also a great advantage in the facility with which the power may be subdivided, and there appears to be no doubt that in future coal mining, electricity will be much used for coal cutting, tunneling, hauling, pumping, etc., as well as for lighting.

THE GREAT ENGINEERING FEAT IN UPPER INDIA.—An article in the Allahabad *Pioneer* gives some interesting particulars concerning the tunnel that has just been completed through the Khojak on the railroad from Quetta to Candahar. The Khojak Pass is 7500 feet above the sea and about 2000 feet above the level of the surrounding country. The tunnel pierces the range at right angles and its course is therefore due east and west, and it enters the hill at about 1000 feet below the crest of the pass. The length of the tunnel is two and a half miles and it will carry a double line of rails. The magnitude of the work is testified to by the banks of rock at the months of the tunnel and at the pit-heads, which are said to be quite altering the landscape. One curious discovery made during the progress of the work, as the result of an investigation into the cause of certain mysterious explosions, was that it was proved that "combustion had arisen inside a case of blasting gelatine."

BRIDGING BEHRING STRAITS.—"They can talk about my uncle as visionary and a mild lunatic all they please, but the day will come, and it is not so far off, either, when he will be recognized as a thoroughly sensible, though bold, engineer." So said William Henry Gilpin of Pueblo, Col., at the Hoffman house, New York, recently. Gilpin has been for the last two years with his uncle, Wm. Gilpin, ex-Governor of Colorado, in a tour of reconnaissance on the Northern Pacific Coast. William Gilpin believes that there is no serious obstacle in the way of building a railroad which will join the United States and Russia by way of Siberia, Behring straits, Alaska and British America. The only apparent difficulty is in crossing Behring straits, but this difficulty is only apparent. The straits are only 40 miles wide, and in the middle lies an island big enough to hold New York, Brooklyn and Jersey City combined. The water is nowhere more than 40 feet deep, and there will be no trouble in erecting piers on a hard bottom.

THE IMAGINATION IN ENGINEERING.—The imagination is a pretty powerful factor even in the matter of engineering. The engineer knew this who once said that if he could find a bright paint that would stand in his fire-box he could obtain any number of commendations as to the splendid condition of his fires; but evidently the engineer did not know it, who once said that the sunlight put out his fires. The sun shone for a few minutes into the fire-room and he was ready to prove it to any one by opening the furnace door when they could see the fire become less bright. He did not consider what a powerful light the fire had in the sun to contend with.

A NEW CANADIAN SHIP CANAL.—The Canadians, who have shown a great deal of enterprise in the matter of building ship canals and in other wise providing for the increase of transportation facilities through their territory, have now under contemplation another scheme which will shorten the route between Chicago and Toronto some 600 miles. It is no less a plan than the building of a ship railway from the Georgian Bay about 66 miles to Toronto.

A COMPANY to utilize underground water for irrigation and other purposes has been organized at Pueblo, Col. The projectors claim to have discovered a point where by placing a dam on the bedrock of a valley 500 yards wide, a flow of a million gallons of underground water per 24 hours will be stored.

JAPAN AND CHINA.—While Japan last year celebrated the completion of 1000 miles of railway, China has at present only 87 miles of road; but a decree of the Chinese Emperor, directing that work on a railway 700 miles long should be undertaken, has been welcomed by the ablest statesmen of the Empire, who have all declared themselves in favor of the proposed improvement.

ELECTRICITY.

Electrical Railways.

Their Success Established Beyond a Question.

In a recent lecture at the Franklin Institute, Philadelphia, Capt. Eugene Griffin said: "The success of electrical propulsion has been established beyond a question. It is only a matter of time, and that a short time, when it will replace the horses on the majority of our street railways. It is only a matter of time, a somewhat longer time, perhaps, when it will be the propelling power on all our elevated railroads, for the elevated roads possess ideal conditions for the application of electricity. It is within the bounds of possibility that our steam roads will be run with electricity; certainly this power offers many advantages for the suburban traffic in the vicinity of large cities. The possible utilization of hitherto neglected water powers will be one of the factors in determining the extension of electrical propulsion in this direction. Already we see the beginning. The West End Company of Boston is building longer cars, with radial and double swiveled trucks. The New York elevated roads are anxiously seeking a solution to the problem of how to enlarge their carrying capacity without rebuilding or materially altering their superstructures. Longer trains are requisite to meet the increased demands. The limit of the capacity of the present locomotive has been reached. Increased weight in the locomotive means an immense expenditure for strengthening or practically rebuilding the roadway. Cables are not feasible, as the strain on the grip would not permit of long trains, and it would be difficult to combine speed and safety with any considerable increase in the number of trains. Cables would not permit of satisfactory switching arrangements at the termini and elsewhere.

Electricity offers the best solution. Equip each car with motors. Flexible electrical connections can easily be made from car to car, as is now done on surface roads, to light the tow cars, and the whole train controlled by the driver on the front platform of the leading car. Electric, vacuum or air brakes can be used in the same way. It matters not how many cars we have in a train—one or fifty. Each car adds its own power and all work together. There is no dead weight to pull, as in the case of the locomotive. The passengers themselves furnish the weight for traction. The switching arrangements present no difficulties whatever. The motors can be reversed and run equally well in either direction. The train can be controlled from either end and any increase or decrease in the number of cars will not affect the controlling mechanism. "It is difficult to conceive of a more flexible system. It seems to be the ideal system for the elevated roads, and is bound to be adopted in the near future."

Still Further Evidence.

Prof. Elihu Thomson, in speaking on "The Problems of the Future," says: "In the near future railways will be run by electricity; not the small roads, I mean, but really the large ones connecting cities, and there is no reason why we should not expect higher speeds than we can attain at present with our steam locomotives. There we have reciprocating parts that must be put in motion, stopped and reversed continually, while in the electric locomotive we have the simple rotary motion, which is all we need, which makes it possible accordingly to run at a much higher rate of speed. Although the steam locomotive has been very much improved, yet it can hardly compare with the economy of stationary engines, placed where they can have an abundant water supply for condensing purposes. We can, therefore, by employing stationary engines and electric roads, do away with a great deal of unnecessary weight, and the moving parts being symmetrical, we can attain a much higher speed, say a hundred miles an hour. This would be a grand step forward, which would save us a great deal of time. It might even be possible to reach a speed of 150 miles an hour. It simply depends upon finding the method of applying sufficient power, and building the locomotives to suit, arrangements being adopted to keep the cars on the track."—*Scientific American.*

ELECTRICITY AS A MOTIVE POWER.—New England manufacturers are beginning to introduce electricity into their factories as a motive power by subdividing it into units. It is found that such a method results in a considerable saving of power over the use of a single motor for all work. The first cost of a number of motors is greater than if a single motor was used; but the saving soons covers the extra expense. A shoe factory at Brockton, Mass., divides its electric power into three parts. Formerly, one motor of 25 horse power ran all the machinery. The division, it is estimated, saves over one-fifth of the former expenditure for power. With a single motor the full power had to be constantly kept up; by dividing, one motor can often be left at rest, resulting in a material saving of power.

MECHANICAL PROGRESS

For Reducing the Cost of Steam.

New devices in boiler and furnace construction are constantly being proposed, to reduce the cost of making steam. Other devices in the way of substitutes for water, such as ammonia, bisulphide of carbon, etc., have also been tried and abandoned as impractical. One of the latest propositions is that of a French engineer, M. Tellier, who proposes the use of

Gas and Steam in the Same Boiler.

By this scheme, M. Tellier claims to be able to produce motive power by using a combustible gas, employing the heat generated by its explosion to generate steam, and the vapor of ammonia. When the gas has operated on the piston, it escapes at a temperature of about 400 degrees into a generator, where steam is produced, which is used to act upon the opposite side of the piston from the gases. There are two advantages claimed for this—the high temperature due to combustion of the gas prevents cylinder condensation, and the steam assists in lubrication. The completed machine for which this claim is made will consist of two cylinders, one making its forward stroke under the action of the explosive gases, and its return stroke by the action of steam; the other is operated entirely by vapor of ammonia. Under these conditions, says M. Tellier, there can be no doubt, theoretically or practically, that .44 pounds of coal per horse-power per hour is an economy which can be secured.

Steam by Electricity.

Hints have recently been thrown out of a device for making steam by the direct action of electricity, which has been put in operation, experimentally, in New Orleans. The character of the machinery employed for this purpose, says the *Times-Democrat* of that city, has been jealously guarded; but a reporter managed to get into the room in which the plant is located, and this is what he found:

To a battery of two 20 horse tubular boilers, a 10-horse engine and boiler is temporarily connected to heat the water in them; steam is first raised in a small boiler, and a dynamo used to produce electricity. The flues in the large boiler are filled with asbestos, the ends are connected with a dynamo, and the passage of the electricity through the asbestos heats it to an intense degree, causing a rapid rising of steam. When the required pressure in the large boilers has been attained, the engine driving the dynamo is attached to the large boiler, and the work goes on as before.

In this way it is claimed that but 25 per cent of the power of the large boilers will be required to furnish 40 horse-power, leaving three-fourths of the power to be applied to other purposes. It is claimed that the power can be supplied in this manner to any required amount. The 40 horse-power could be used after starting to start up a 160 horse-power, and keep it moving without any cost whatever outside of keeping up the machinery. This is the first instance on record where power could be increased; nature has always worked the other way and demanded that a stronger should work the weaker, as the 40 horse-power to drive 10, and if this proves a success as is claimed, the company have the biggest discovery ever made in America, that will rank next to the discovery of steam power itself.

Contraction and Expansion in Steam Boilers.

One of the severest tests of the strength of a steam boiler is due to the unequal expansion and contraction of its different parts, owing to the effects of changes in its temperature. In the case of flue or tubular boilers, in which the flues or tubes are more directly exposed to the influence of heat than the shell, the strain thus developed is tremendous, the tubes or flues, or their material, expanding lengthwise with a force calculated to tear the heads out of the boiler. Where the flues are placed very near the bottom of a boiler, in which case the pressure is all on the lower side of the heads and the plates that keep them together, it is not unusual for these plates to be ruptured or the seams sprung underneath, causing troublesome and often dangerous leaks.

The smaller the proportion of the surface of a boiler that is exposed to the heat, the more active will be the effect of the expanding and contracting forces, and in the case of some boilers, set more than half exposed to the influence of the atmosphere, the tremendous power exercised by the expansive heat of the fire below and the contraction due to the low temperature above, are almost enough to tear the boiler to pieces.

It is the unequal expansion of shell and tubes and of the upper and lower shell, that really does more injury to a steam boiler than the expansion and contraction due to changes in pressure of steam; the leakage and cases of ruptures that so often occur in the lower seams and along the bottom of horizontally fired boilers are unquestionably due to these causes, and in very many instances forced firing in getting up steam on first starting the boiler is to blame.

To avoid the injuries so often caused to boilers in this manner, it is necessary therefore, to exercise great care in raising steam in new boilers or those that have been blown out and allowed to cool down.

The fire should be raised moderately and gradually and the boiler moderately filled with water, so that the increase in the temperature may be gradual. In cooling off a boiler the same care must be exercised. The plan adopted by some engineers, of turning a stream of cold water into the boiler as soon as it is emptied, cannot be too severely condemned, nor should the furnace doors be too suddenly thrown open or any other proceeding taken that will result in suddenly lowering the boiler temperature, a rapid decrease in the heat being quite as bad for the safety and durability of the boiler as the immoderate and unequal increase above referred to.

AMERICAN-BUILT CARS FOR EUROPE.—The Jackson & Sharp Works, at Wilmington, Del., are building passenger cars for the railways in France, Spain and Austria. Mr. William Voss, writing about the cars after a visit to the works, says: They are a curious mixture of European and American practice, and are built according to complete sets of drawings sent over. Of course it is sectional work, like that sent to South America. These cars are about 50 feet long, some of them day coaches and others of the Mann bondofr style of sleeper. They have combination wood and iron sills, *bogie* trucks, the old country draw-hook and buffers, etc. All the heater and water pipes are of copper, windows run in brass guides (a very good but expensive thing). There is a vestibule at each end, but they do not touch like ours, being about four feet apart when coupled, and iron aprons and railings form the bridge. The entrance is through the vestibule and steps like ours, but *different*. The exterior is mahogany, natural wood finish. Roof much like ours, and is covered with canvas and sheet copper on ends and at eaves. Some of the cars have been shipped, six or 12 more are almost done, and a lot of six is just being erected.—*National Car and Locomotive Builder.*

A LARGE GIRDER FOR SAN FRANCISCO.—The Keystone Bridge Co. has just completed a girder for the New City Hall of San Francisco, which is the largest ever made in the United States, so far as the members of the firm know. It is 105 feet long and weighs 70 tons. A contract for two girders was given to the company. The materials for the second one are now being prepared. The girders are intended for the ground floor of the building. The great problem now is to transport it to the Pacific Coast. The Chicago & Northwestern and Union Pacific roads have undertaken the job. The long monster recently was lying on three of the largest freight cars obtainable on the Allegheny tracks. It was necessary to put in additional trusses to distribute the weight evenly on the three cars. The way it is placed in the cars will allow it to go around the curves all right. The usual plan for shipping girders is to carry them in pieces and have the plates riveted together at the place of destination. The company was afraid they didn't have the facilities on the Pacific Coast to do the riveting. The second one will not be built until they see whether or not it can be transported.—*Pittsburg Dispatch.*

AMERICAN GENIUS.—It is one of the most marked characteristics of American skill and genius that whenever any new industry is started in this country, which materially depends upon the use of machinery for its successful competition with other localities, the desired success is largely brought about by improved devices for its prosecution. Until within a few years it was thought impossible to compete with European countries in the manufacture of plate glass. The business, however, was started and is now firmly established. To show how this has been accomplished, it need only be stated that the German polishing machine formerly in use was bought at a cost of $10,000. Within the past six months American mechanics have constructed a new polishing machine whose cost will not exceed $2700, and thus early in the trial it has demonstrated its superiority over its foreign predecessor by doing the same work regardless of area, in two hours less time, and giving a better finish to its product.

PROPULSION OF BOATS BY ELECTRICITY is effectually exhibited at the Edinburgh Exhibition. On the Union canal, which skirts one side of the exhibition site, four launches, each 40 feet long, 6 5 feet wide, drawing two feet of water and carrying 40 persons, are run by storage batteries. The machinery has been supplied by M. Immisch & Co., of London. The charging plant consists of an Immisch dynamo and a 25 b. p. engine, all the launches being charged at the same time, usually at night. A launch can run 10 to 15 hours on a single charge. Details as to weight of storage batteries and time taken for charging are lacking.

THE HALPIN SAVAGE TORPEDO, lately inspected by the Board of Naval Engineers, carries its own motive power in the shape of storage batteries, and only a very light wire cable is paid out, by which the operator on shore controls the steering gear. The torpedo proper has an independent means of propulsion by rocket composition which can be fired electrically. The mechanism is so arranged that when a net is hit the torpedo is disengaged, dives underneath the net, comes up and is exploded when close to the hull.

SCIENTIFIC PROGRESS.

Can Science Control the Elements?

The frequent occurrence of cyclones, tornadoes, cloudbursts and other exhibitions of elemental fury, accompanied often by appalling destruction of life and property, forces increased attention by thoughtful men to the question whether science is and must always remain powerless to guard against such dangers. Man has already successfully grappled with many foes to human health and safety, encountered in various forms of disease, in the pursuit of ordinary vocations and in connection with the means of transportation. But the cyclone which comes without warning from the sky, scattering sudden death and destruction along its path and as suddenly disappearing, leaving a blue sky over the misery which the storm spirit has created, seems naturally to be a demonstration of omnipotent power which human art must be powerless to control or mitigate.

Yet science in these later days sees no boundaries to the possibilities of its power, and in view of the astonishing discoveries and achievements which the mind of man has already been permitted to make, it does not require audacity or the exercise of extravagant faith to believe that eventually man will find that to no small degree he has power also over the elements in their most dangerous manifestations.

Not many years ago, man said that they were utterly powerless to protect themselves against the thunderbolt which leaped from the sky, carrying fire and death to the earth. But Franklin devised the lightning rod, which now conveys the fire shaft to the ground without injury to man or his possessions. Many at first believed it to be an impious thing to attempt thus to interfere with the messengers of the Almighty, and the Roman Catholic church denounced the lightning rod as an invention of the enemy of mankind. But in these days men believe that any comfort or protection which human genius is permitted to discover for the benefit of mankind is not only proper but to be received with thankfulness, and the suggestion of attempting to diminish the dangers from violence of the elements is no longer looked upon as impious, nor, in view of what science has already achieved is it safe to pronounce any scientific undertaking impossible or preposterous.

These remarks are suggested by the following communication which we have received from a civil engineer of extended experience whose name is familiar as the chief engineer of one of the southwestern railways:

Generally speaking there are few evils which cannot be overcome or whose effects cannot be somewhat ameliorated by some device of man, and I am constrained to ask through your paper for some suggestion as to the probable best cure for the evil effects of what is generally termed a cyclone. As the west becomes more densely populated, the loss of life will increase as a result of our twisting storms, and may it not be advisable to intercept nature and bore a hole artificially and continuously through the air to cooler regions aloft rather than to allow nature to suddenly and violently try to seek an equilibrium in the atmosphere? Plainly, could out steel stand pipes, say 500 feet in hight, be distributed in the most thickly inhabited localities, with powerful fans either run by water or otherwise, which would do during the dangerous period continuously what nature does violently and suddenly?

There is another subject which interests the west—the rainfall. Gen. Ruggles, an officer of the U. S. army, suggested and tried to get the State of Texas to appropriate a sum to be used in experimenting with balloons, freighted with some explosive, which at a certain hight by a system of clockwork would be exploded and tend to mingle two currents of air, and if they happened one to be cold and the other to be warm and charged with moisture, he thought the moisture would be precipitated on the land. The legislators did not think the general's ideas were sensible, or possibly they may have been deterred by the consideration of additional laws to be enacted to protect the brick-maker against the hungry farmer.

Our correspondent's suggestion is submitted for consideration. While it may not indicate a practical method of dealing with cyclones it may serve to direct the attention of scientific men still more earnestly to the subject and evolve results which shall bless mankind. If the lightning rod draws the electric fluid harmlessly from sky to earth why may not a similar principle be applied to providing escape-ways for the concentrated violence of the air from earth upward? The other suggestion, concerning the production of rain, is directly in accordance with scientific principles already developed beyond the region of theory, but for which more definite means of practical application are still to be desired.—*Railway Age.*

IS THERE MORE THAN ONE ELEMENTARY SUBSTANCE? — Analogy forbids us to believe that down to a certain limit of dimensions that we call molecules, the constitution of matter is of a wholly different sort from that which appears on subdividing the molecules. It is an equally incredible assumption that all atoms of the same element are so many independent creations, exactly alike in every respect. Then, as our knowledge increases, the distinctions between the chemical elements are becoming less marked and their relations to each other more intimate. They are beginning to appear not as isolated units, but as links in a complex network, which presents an unbroken continuity throughout. The recent study of the rarer earths leaves us in doubt whether we have an indefinite number of elements, or only one under innumbered manifestations; and the later results of spectrum analysis seem to indicate quite clearly that at the high temperatures of the sun and the fixed stars, many of our terrestrial elements are decomposed. From a mathematical analysis of the spectra, Grunwald maintains—and supports his conclusion by a remarkable array of confirmatory measurements—that the remarkable solar spectrum line called helium, and the equally well-marked line of the sun's corona, come from two constituents of hydrogen gas, the first of which is somewhat heavier and the last far lighter than hydrogen gas.—*Manufacturer and Builder.*

Seeing by Electricity.

It is said that modern electricians may succeed in constructing a device that will do for the sense of sight what the telephone does for the sense of hearing; but the prospects of such an achievement are not particularly bright. The possibility has been demonstrated experimentally, but the practical difficulties in the way of carrying out the idea are very great.

It is well known that certain salts of copper and silver, for example, generate electric currents when exposed to the light, and, conversely, electric currents will produce in these salts changes corresponding to those made by light. If a strongly illuminated object is placed in front of a transmitter covered with such a salt, electrical currents will be generated which will vary in intensity according to the intensity of the light falling on different parts of the surface. If now, these various currents were carried to a receiver similar to the transmitter, they would produce on its surface changes like those wrought by light on the surface of the transmitter.

Another apparatus has been proposed, based upon the property peculiar to selenium that its electrical resistance changes with the intensity of light. For a transmitter the selenium cells are arranged in square, like a checker-board. The greater the number the more efficient would the apparatus be. Each of these is connected with an electro-magnet in the receiver. The latter is composed of a mirror constructed of thin strips of steel, to each of which several of the electro-magnets are attached. A strongly illuminated body being placed in front of the selenium transmitter, the electrical resistance of the various cells varies according to the intensity of the light, as in the case of the salts of copper and silver. The various currents affect the electro-magnets in different degrees, the result being that the strips of steel are bent irregularly, turning the mirror into an aggregation of surfaces, very slightly warped, which will throw an image on a screen.

The main difficulty in the way of the realization of such an idea as seeing by electricity lies in the necessary complexity of an apparatus which shall enable innumerable points in the transmitters and receivers to be actuated simultaneously in perfect independence and also in perfect correspondence; but it is quite possible that further experiment will bring into actual use what might be something more than a mere plaything. In defensive warfare a telescope of indefinite length would certainly be of value. With buried wires and concealed visors a general might watch his adversary's movements at times when this would mean victory instead of defeat.—*Electrical World.*

LANGUAGE OF FISH.—Mr. W. A. Carter, in a recent lecture on "Marine and Fresh-Water Fishes," said that fish have the power of influencing one another by sounds and action. He had observed a shoal of carp following the lead of a single one, which conducted them to a quantity of food at a considerable distance away. He had also noticed that certain fresh-water fish, such as trout, were subservient to a ruler, who might be seen swimming at the head of his tribe. The same was possibly the case with some marine forms, like the herring and bass.

THE EIFFEL TOWER.—The London tower designs, for which prizes were offered, have all come in and been examined. The first prize of 500 guineas has been awarded, also the second of 250 guineas, and a third has been given special mention; but all three of these designs, and still more the 60 or 80 of others, were so far inferior to the Eiffel tower in dignity and grace as to make it ridiculous to prefer them to a mere enlargement of the latter. This the committee in effect states, recommending no plan for construction.

ELECTRIC-LIGHT BUGS.—When the first Atlantic cable was laid scientists asserted that an insect would soon appear which would attempt to destroy it; and sure enough in a short time an insect, not classified by entomologists, began its work on the insulators. The electric-lighting system in large cities seems also to have developed a similar condition of things in the shape of what are called electric-light bugs; and singularly, each system of lighting has its own peculiar insect satellite.

BIRDS ON THE PERCH.—The reason given why birds do not fall from their perch is because they cannot open the foot when the leg is bent. Look at a hen walking and see it close the toes as it lifts its foot and open them as it touches the ground.

TABLE OF CONTENTS.

EDITORIALS.—A Lead-Smelting Furnace, 67. Passing Events; Comstock Mine Management; Cable Railway Anniversary; Ancient Lake Cliffs and Terraces, 72. Cable Patent Infringement; The Comstock Mines; A Bird's-eye View of the Yosemite, 73.
ILLUSTRATIONS.—Sea Cliffs and Terraces Caused by the Waves of Lake Bonneville, Utah; A Typical Modern Lead-Smelting Furnace Plant, 67. Relief Map of the Yosemite Valley, 73.
CORRESPONDENCE.—The Gold Belt of Northern California; The Oathill Quicksilver Min.; In Sierra County, 68. San Bernardino County, 69.
MISCELLANEOUS.—Mining Outlook of Nevada, 68. A Grand Redwood Reservation. 69.
USEFUL INFORMATION.—Suggestions by a Photographer; Artificial Honey a Myth; Our Population; The Inventor of the Letter Copying-Press; Miscellaneous, 72.
GOOD HEALTH.—The Prevention of Sunstroke; Seven Hours' Sleep at Least; Poisoned by Lead Dust; Nose Bleeding; Miscellaneous, 72.
ENGINEERING NOTES.—Relative Costs of Transmission of Power; The Great Engineering Feat in Upper India; Bridging Behring Straits; The Imagination in Engineering; Miscellaneous, 72.
ELECTRICITY.—Electrical Railways; Electricity as a Motive Power, 72.
MECHANICAL PROGRESS.—For Reducing the Cost of Steam; Contraction and Expansion in Steam Boilers; American-Built Cars for Europe; A Large Girder for San Francisco; American Genius; Miscellaneous, 73.
SCIENTIFIC PROGRESS.—Can Science Control the Elements; Is there More than One Elementary Substance; Seeing by Electricity; Miscellaneous, 73.
MINING SUMMARY—From the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Wyoming, 70-71.
MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 73.
MARKET REPORTS.—Local Markets, Eastern Metal Markets, 73.

Business Announcements.

Passing Events.

Silver reached a higher point in New York this week than it has for five years. Moreover, large quantities are going to London at present, reversing the predictions of the anti-silver men, who said silver would flow to this country from abroad if the silver bill passed.

If the statements of a Redding paper prove true, as reported in our mining summary in another column, Shasta county will be greatly benefited. A rich English company is reported as proposing the purchase of a number of mines and the erection of tramways and an immense mill plant on the Sacramento river. English capital has already been invested in Shasta county mining property to some extent.

There are no new features to report concerning the molders' strike in this city, which has lasted so many weeks. Several more Eastern molders have arrived and gone to work in the local shops. Some, also, have left; but the shops are all running their foundry departments, though with more or less inconvenience.

THE formation is nearly all clay above the gravel in the artesian well at Battle Mountain, where gold was found at a depth of 640 feet below the surface. It is probable that a shaft will be sunk to bedrock to get the gold-bearing gravel out by drifting.

The Comstock Mines.

From the Comstock mines, advices received Wednesday report that the ore in the Ophir winze was widening and improving. The winze in Savage was also improving, as was the Potosi winze, which, it is said, has been turned so as to run into ore. The southwest drift on the 600-foot level in Alpha, when in about 95 feet, cut the east wall of the ledge. In Con. Virginia advices are of an improvement on the 1600-foot level in the mine. On the 630-foot level in Sierra Nevada they were in ore. In Overman the management is not taking out the good ore, but instead are milling ore going below $20. This, it is said, is done so as to break the stock to about $2 a share. Whether this latter report is correct or not, time can only tell. As far as that is concerned, there are reports of slightly lower prices on all the Gold Hill stocks before they will be a buy for something good. In Yellow Jacket, on the 500-foot level, they passed through six feet of ore which will mill $40 a ton, after which an old winze was run into. In Kentuck they are drifting east and west on the 1000-foot level, and at the same time prospecting on an upper level. The official letter from Savage gives the battery assays $4 higher, while Crown Point's is $3 lower and Belcher's $5 lower. Active prospecting work is being done in all the Gold Hill and middle mines.

As far as that is concerned, there is more work, and that, too, of an important character, being done in the Comstock mines than for many years, and if the mines were differently managed there might be a possibility of a genuine mining-stock boom. From Hale and Norcross to Overman there are mines that would be paying dividends if they were conducted on business principles and managed strictly in the interest of stockholders.

Following is a statement of the total ore and bullion yield of the Comstock lode mines during the quarter ended June 30, 1890, compiled from the sworn statements of Superintendents now on file in the office of the County Assessor, Storey county, Nevada:

	Tons.	Bullion.
Con. Cal. and Virginia	35,485	$ 512 879 27
Savage	6,186	90,912 01
Hale & Norcross	13,233	85,749 81
Con. Imperial	212	3,217 60
Overman	4,233	75,943 22
Crown Point	9,960	137,362 35
Justice	2,333	54,104 59
Alta	4,200	40,148 33
Challar	5,881	97,914 94
Yellow Jacket	7,500	105,000 00
Totals	88,993	$1,300,013 62

The above are all official statements except that of the Yellow Jacket, which has not yet been filed. The total exceeds that of the first quarter of the current year nearly $415,000. The next quarterly statements will include the Belcher and Ophir, which have been added to the bullion-producing mines of the lode the current month. The total bullion tax on the above yield is $2448.12, with the probability that the Yellow Jacket report may swell it to $3000.

Cable-Patent Infringement.

A decision of interest to the people of this coast comes to us from the U. S. Circuit Court, Northern District of Iowa, Western Division.

Many of us remember the beginning of cable roads, and it is our boast that San Francisco was not only the pioneer, but that it still leads the world in this most useful class of street railways.

To us, the name of A. S. Hallidie is indissolubly connected with the inception and progress of this system. His early inventions in this line were numerous and have been generally adopted. That one commonly known as the "slot switch," and covered by letters patent of the U. S., No. 179,016, dated June 20, 1876, was adopted and used by the Sioux City Cable Railway Company, without the license of its present owner, the National Cable Railway Company of New York, the assignee, east of the Rocky mountains, of that and many other cable-road patents of Mr. Hallidie and his associates (the Pacific Cable Railway Company of San Francisco being the Western assignee).

Upon a bill in equity, filed to restrain this infringement, Judge Shiras, in a well-considered opinion, has recently decided in favor of the National Cable Railway Company, sustaining the patent and holding an infringement on the part of the Sioux City Cable Railway Company,

Mine Management in Nevada.

In the editorial department of the New York *Engineering and Mining Journal*, under date of June 28th and July 12th, will be found a severe commentary upon the managers and their management of the Comstock mines. And the *Journal* compliments us by saying: "We are glad to note that the San Francisco MINING AND SCIENTIFIC PRESS is keeping up the agitation—not that we have a very hopeful expectation of any great practical gain to attain by it, for Comstock peculiarities are too deeply rooted to be overturned by denunciation, or, as it seems, by law. But purely as a matter of principle, it is well to protest, even if ineffectually."

Do these words, quoted from one of the editorials mentioned, convey to the ordinary reader why so many of our Pacific Coast mines fail to draw capital from Eastern capitalists? Is it true that our laws cannot be enforced against the very few men who manage these mines, and in behalf of the thousands upon thousands of stockholders who own jointly therein? We sincerely hope it is not true. Still it is evident that the General Government should take this matter in hand and make a thorough investigation of the charges preferred and now in the hands of the Government officials. These charges should be investigated in order to remove the stain upon our mining industries. If the charges are false, let the parties bringing them suffer; if they prove true, let the Government do its duty by a body of its citizens who claim to be oppressed by severely punishing the oppressors.

"An investigation has been made," said the President of the Mining Stock Association in a recent interview had with that gentleman, "and it revealed a strange state of affairs. Our association, consisting of stockholders in mines, have been struggling with the courts, aided by brief notices from the press, for the past year to get some representation for stockholders in the distribution of the profits of the mines in which they own. Our association does not object so much to the $7.00 per ton paid for milling as it does to having at least 50 per cent of the value of their ores run off in tailings and slime by the mill companies.

"We think the mill company can mill ores at $3 00 per ton and make a profit; but our objections have been put in writing, and not only filed with the mining companies who are robbing us, but we have preferred charges against their using the U. S. Mint at Carson in connection with the bullion which they take from the ores and fail to return to the mines. The bullion belongs to the mines. All bullion taken from ores of the mines and not returned to them by the mill companies has been stolen; and we are preparing to recover that which has been stolen. Take the Hale and Norcross and Savage mines for example. At the annual election of the Savage mine, one year ago, we filed a protest against the mill steal, and made a demand, at that time, for the Directors to commence action for a recovery of the bullion taken from the companies' ores and not returned to the company. They have had one year to make up their minds. Soon we will show them what we are trying to do. In that protest—a copy of which we have on file—you will see that we use their own figures to prove that formerly the mills were required to return 65 per cent of the mine assay, and by their figures we also prove that the mill company returned 35 per cent only, thus reversing the order of things, and retaining that portion which they formerly were obliged to return.

"There are figures on their bullion record books in Virginia City showing that 70 per cent of the mine assay has been used as a base of settling with mills. Our association made a further demand of the Savage Company at that time. They demanded that the directors order the superintendent to report his mine assay, weekly, to the San Francisco office, and by so doing obey the laws of our State. They have refused to comply with the demand, and have stood off an action in the courts, by delays, which was instituted to compel them to give all stockholders the knowledge which they selfishly and illegally withheld. In refusing to obey the law, although their superintendent has testified under oath that he makes the mine assays daily and is willing to send them to the office when so ordered, it shows the contempt they have for our laws, and the boldness with which they confiscate the rights and property of stockholders.

"To further illustrate our object, take the Hale & Norcross reports for the first few months of 1889. In February they milled 3973 880 2000 tons. The mine assay of the ore which the stockholders were not allowed to see, is claimed to be about $56 per ton. When the mill company had put it through their new process, it assayed about $22 75 per ton, and the mill company returned to the mine $19 65 per ton. Here is an example of how $50 ore is made to pay less than $20 per ton. You may ask how it is done and we can only explain the discrepancy by calling your attention to the slimes and tailings. In the first place, it does not seem to matter how rich the ore is when it comes from the mine. You will find that the mill company report their assays somewhere around $20 per ton. That seems to be an understood figure. Out of such ore, ranging from $20 to $25 per ton, we have assays taken from the tailings of about $9 per ton; and assays of slimes, taken from the sluice-boxes leading to the slime ponds, that will go over $100 per ton.

"We think such evidence sufficient explanation of how owners of mills get very rich at the expense of stockholders in mines. Against such action we are patiently awaiting the action of our General Government in regard to charges preferred by our association; an action we have in the Superior Court to compel them to furnish the stockholders of mines with the true assay of their ores, and a general complaint we propose to compile for an accounting of all bullion taken from the ore of the mines. It must be apparent to any business man that these mill companies have been doubly compensated for crushing the ores of the mines when they are paid $7 per ton. The bullion coming from those ores is the property of the mines. Every ounce withheld from the mines and illegally appropriated by parties other than mine-owners, will have to be accounted for by the mill companies and those people who have acted as trustees for all stockholders.

"We do not think half of the men acting as trustees in mines, fully realized the grave responsibility they have taken upon themselves when they turn property, held in trust for all stockholders, over to mill companies to be looted. Somebody will have to respond when the day of accounting comes; and that day always comes, be it sooner or later."

Ancient Lake Cliffs and Terraces.

The facility and certainty with which the vestiges of ancient water margins are recognized and traced depend on local conditions. The small waves engendered in ponds and sheltered estuaries are far less efficient in the carving of cliffs and the construction of embankments than are the large waves of larger water bodies. The element of time, too, is an important factor. A system of shore topography from which the parent lake has receded is immediately exposed to the obliterating influence of land erosion and gradually loses its character and definition.

The wave-built terrace is distinct from the wave-cut terrace in that it is a work of construction, being composed entirely of shore drift, while the wave-cut terrace is the result of excavation and consists of the pre-existent terrane of the locality. The wave-cut terrace is overlooked by a cliff rising from its upper margin, and only appears on the margin of an open basin broad enough for the propagation of efficient waves.

The great Lake Bonneville (of the Quaternary period), in the division of the Great Basin of Utah, is known by the records on its ancient shore-lines. All about the Great Basin of Utah the lower slopes of the mountains are skirted by level tracings—not a single line merely at a single level, as in the Coast Range of California, but a series of lines at many levels, testifying to a system of oscillation of an ancient lake. The highest water-line is 1000 feet above the level of the Great Salt Lake, and over every foot of the intervening profile can be traced evidence of the action of waves. The point of outlet of this ancient lake was at the northern extremity of Cache valley. The sill over which the water at first discharged was soft, and yielded easily to the wear of running water, permitting the lake level to be rapidly lowered, but eventually a reef of limestone was reached, by which the erosion was checked and held at a nearly constant level until the outflow was finally stopped by climatic changes which diminished the water supply.

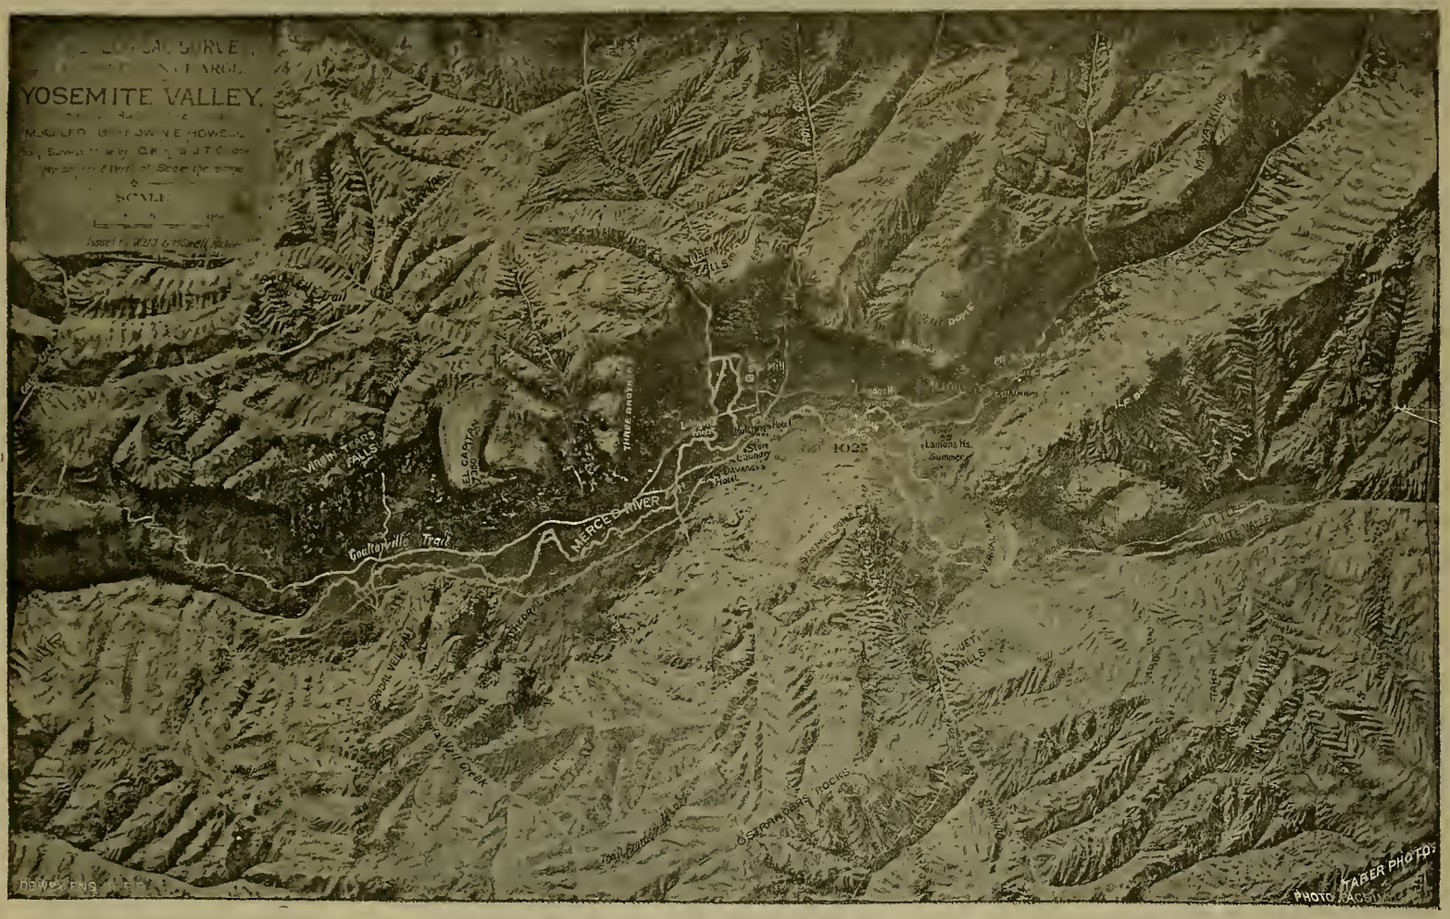
The history of this great lake is written by wave-sculptured topography and by lacustrine deposits. The Bonneville basin is surrounded by and interspersed with mountains. Form and substance conspire to prove that the lake had a beginning as well as an end, and before its inception the lake basin was for a long time subjected to the ordinary laws of sculpture by the action of rain. Nevertheless, the Bonneville shores are almost unmodified.

On the first page of this number of the PRESS is reproduced a view of a portion of the shores, showing the sea-cliffs and terraces carved by the waves of Lake Bonneville, on the north end of the Oquirrh range, Utah. This is only one of the many evidences of the existence of this great Quaternary lake.

A Bird's-eye View of the Yosemite.

The Yosemite season is at its hight and the valley is receiving its annual throng of visitors from all quarters of the world. To those who have visited the valley and to those who contemplate pilgrimages thither the relief map which we present on this page will be welcome. So far as we know it is the first presentation in a newspaper of this unrivaled method of portraying this grandest feature of California topography. We reproduce the engraving from original sources by the photo-facsimile process of the Dewey Engraving Co. To one who studies closely the picture new excellencies continually appear. Like all relief maps it gives impressions and knowledge of conditions which are, by the nature of the case, wholly lost in a flat map, and it conveys a knowledge of the collocation of the features of the country which cannot be learned by series of isolated views no matter how excellent they may be. In fact it supplements admirably the impressions gained by personal inspection of the valley, for no one can obtain a point of view which will yield a knowledge of the topography such as the topographers have patiently created by their methods of almost countless measurements. The sources of information employed in the representation and the persons engaged in the honorable work are stated in the upper left hand corner of the picture.

The student of the valley will gain from this map both actual knowledge of facts and impressions of the grandeur of nature's handiwork. It discloses the general trend of the main valleys and its tributary gorges. It shows the water-courses, the trails to reach notable points, and the manner in which the visitor gains giddy hights by practicable routes. It gives also the elevation of the most noted points, and by implication as well as by the shadows the depth of the depressions below them. It will prove of permanent value to all acquainted with the valley as a skeleton around which they can place the firm flesh of their experiences and adorn with the garments of their imagination.



RELIEF MAP OF THE YOSEMITE VALLEY AND ADJACENT COUNTRY.

THERE are probably 30,000 tons of tailings, accumulated at the Morgan mill, up on the Comstock, that will be run through the pans after the stamps are hung up.

SINCE the Humboldt Reduction Works started up in the latter part of May on ore from the Winnemucca mine, 14 bars of bullion, weighing from 80 to 100 pounds each, have been shipped.

Cable Railway Anniversary.

Seventeen years ago yesterday (Aug. 1, 1873,) the trial trip of the first cable railway was made at 4 o'clock in the morning on Clay street in this city.

The road as originally constructed ran from Kearny to Leavenworth street, and after making this trial trip and one in the afternoon of same day, both of which were successful and satisfactory, the road was stopped for a month to extend the tube one block farther, and it began running again permanently on the first day of September, 1873.

The terms of the franchise required the road to be in operation by the 1st of August, hence the necessity of making the trial trip on that day.

The plan had been criticised, and no confidence was expressed by those competent to judge of the enterprise. The inventor, Mr. A. S. Hallidie, after two years' effort had despaired of having the system tried, until Messrs. Joseph Britton, Henry L. Davis and James Moffit came forward and joined him in the cost of its construction. On the first trip, on a foggy morning in August, the man detailed to engineer the dummy, when all was ready at top of the hill to make a start, weakened, and Mr. Hallidie took the grip and made the trip down and up. He is thus the oldest gripman in the country.

It was three and a half years after this that the next cable road was built, which was on Sutter street, followed in some course of time by California, Geary, Union and Market streets. The Omnibus Cable Co. is the last cable road built in this city and it is interesting to note that it was that road which first determined Mr. Hallidie to improve the street railroad system.

Running up Jackson street between Montgomery and Stockton, extra horses had to be used to haul the cars of the Omnibus Company up that steep street, and the horses in struggling up the hill with heavily loaded cars, in the winter, often fell and were dragged down the hill; the brakes not being able to hold the car. Humanity for the horses prompted Mr. Hallidie to find a better way, resulting in the Cable Railway System.

Silver Shipments.

The predictions of the anti-silver men have not only not been verified, but have been completely reversed, since large quantities are being shipped to London instead of flowing into this country. Over a million and a quarter ounces went last week and as much more this week. A month or so before the passage of the Silver bill London sent a million and a half ounces to this country because they thought the bill would not pass. Now the flow has set the other way.

On August 13th the Government will begin to buy 4,500,000 ounces of silver monthly for which certificates will be issued and the bullion stored. This demand will be met by the silver owners and mines that have not paid will again become profitable since the discount on the metal is so much reduced. Moreover, England wants silver just now to send to India in payment for wheat and cotton and makes an earlier demand than usual because of the action of this Government on the silver question.

The men who own the mines in the silver-producing States can now realize something from their investments. For some years the price of silver has been depreciated and great loss has occurred owing to the heavy discount. Now, however, that the price has advanced so materially, with probability of a still further increase, this discount naturally lessens sufficiently to admit of profit on ores heretofore unworkable. This ought to, and doubtless will, start up many low-grade mines which have been lying idle during the depressed condition of the white metal. Districts and camps which have been struggling for existence should once more flourish and give employment to many more miners.

ANOTHER RIVER BED ENTERPRISE.—A special from Oroville, Butte county, says: Parties in this community who held interests in the Cape Union and Cape Creek mining claim, comprising a mile and a half of the Feather river channel, at Oroville, were paid off in gold coin at the bank of Rideout, Smith & Co. to-day by Major Frank McLaughlin. Many old miners who never expected to realize a dollar were made happy with snug fortunes. This is the result of the Golden Feather, which was successfully floated in London, England, May 15th. Work will be commenced on the great mine and numerous other enterprises started, which will tend to build up the town and revolutionize mining. The company represents a capital of $180,000, all paid in.

Causes and Cure of Hard Times.

In seeking to get at the causes of "hard times," we find one that lies far deeper down, far nearer the heart of the matter than any question about free silver coinage, or the tariff, or loaning money on mortgages. These are indeed matters of equity, expediency and (so to speak) convenience; but deeper down lies the fact that the producers and actual manufacturers and *honest* carriers and commission merchants—deeper down, we say, lies the fact that those who honestly do needed work and are content with a fair share of what the world's work produces, are but part (alas that they are so small a part!) of those who enjoy the *products* of such useful industries. However ingenious the plans devised for making money plenty, the honest toilers will still be robbed of their due, so long as wolves, foxes, and locohes are propagated. The deeper cause of hard times is the prevalence of that spirit which breeds parasites and robbers, which allows young men and maidens to grow up with no manly nor womanly longing and resolve to be of use in the world; to grow up concerned only to get all they can—their own share and the shares of others, too, if possible—with no sense of the truth that if "the world owes them a living," it is only as they each one owe the world life-service.

THE Sierra Valley *Leader* says: C. B. Stanley, who came to this State in 1840, is prospecting in this and Plumas county. When he came here there were only 16 Americans and 26 English known to be on the coast. He is 69 years old, hale and hearty. He was at Monterey when Captain Jones hoisted the first American flag, in 1842.

A FIRE at Wallace, Idaho, this week, destroyed the business portion of the town and entailed a loss of half a million dollars.

NEVADA'S POTATO CROP is reported to be uncommonly large this year.

WOMEN CARPENTERS have appeared in London.

PARKE & LACY COMPANY

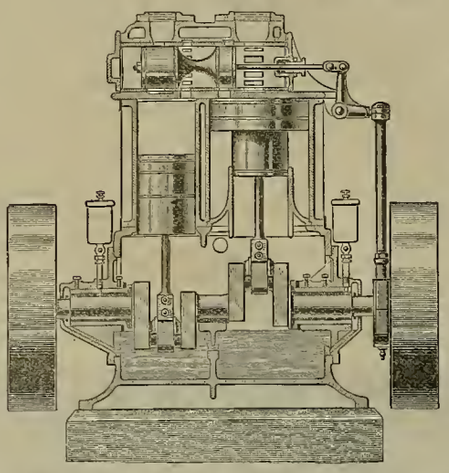
IMPORTERS AND MANUFACTURERS OF

MINING, MILL and GENERAL MACHINERY.

ENGINES, BOILERS, STEAM PUMPS,
AIR COMPRESSORS, ROCK DRILLS,
WALL'S CRUSHING ROLLS,
CONCENTRATORS, PULVERIZERS,
TURBINE WATER WHEELS,
ROCK BREAKERS, DRY JIGS.

Bullock's Diamond Drills

GOLDEN GATE CONCENTRATORS,
GREATEST CAPACITY OF ANY CONCENTRATOR MADE,
One Machine Taking Pulp from 10 Stamps.



SAW MILLS, MACHINE TOOLS,
PLANING MILLS, INJECTORS and EJECTORS
BELTING, PACKING, OILS, LUBRICATORS,
FIRE EXTINGUISHERS,
CENTRIFUGAL PUMPS
ROTARY PUMPS, GANG EDGERS,
CAMPBELL'S STEAM FEEDS,
MILL and MINE SUPPLIES.

GENERAL AGENTS FOR

WESTINGHOUSE AUTOMATIC ENGINES.

SALES DURING LAST FOUR MONTHS:

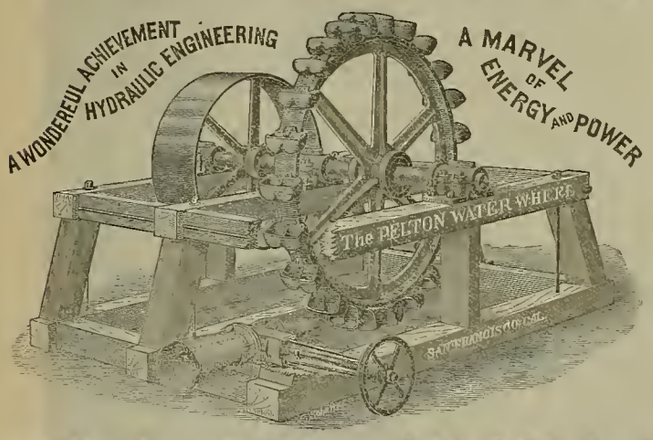
COMPOUND, 44 ENGINES, 5215 HORSE POWER. STANDARD, 99 ENGINES, 4500 HORSE POWER. JUNIOR, 166 ENGINES, 4260 HORSE POWER.

Grand Total, 309 Engines, Aggregating 13,975 Horse Power.

21 and 23 Fremont St., San Francisco, Cal. 189 Clarence St., Sydney, N. S. W.

THE PELTON WATER WHEEL

GIVES THE HIGHEST EFFICIENCY OF ANY WHEEL IN THE WORLD.



A WONDERFUL ACHIEVEMENT IN HYDRAULIC ENGINEERING
A MARVEL OF ENERGY AND POWER
The PELTON WATER WHEEL Co.
SAN FRANCISCO, CAL.

OVER 800 ALREADY IN USE.

Affords the Most Simple and Reliable Power for all Mining and Manufacturing Machinery.
Adapted to heads running from 20 up to 2,000 feet.
From 12 to 20 per cent better results guaranteed than can be produced from any other Wheel in the Country.

ELECTRIC TRANSMISSION.

Power from these Wheels can be transmitted long distances with small loss, and is now extensively used in all parts of the country for generating both power and light.

APPLICATIONS

Should state amount, and head of water, power required, and for what purpose; with approximate length of pipe; also, whether the application is with reference to *Wheels* or *Motors* described below. SEND FOR CIRCULARS.

The Pelton Water Wheel Co.
121 MAIN ST., SAN FRANCISCO, CAL.

PELTON WATER MOTORS.

Varying from the fraction of 1 up to 15 and 20-horse power. Unequaled for all light-running machinery. Warranted to develop a given amount of power with one-half the water required by any other. ☞ SEND FOR MOTOR CIRCULAR. ADDRESS AS ABOVE. ☜

THE GATES

ORE AND ROCK CRUSHER

—IS—

THE MOST IMPORTANT IMPROVEMENT

That Has Ever Been Made in This Class of Machinery.

IT WILL DO MUCH FINER WORK

Than Any Other,

AND AT ONE-HALF THE COST IN WEAR.

The Pelton Water Wheel Co.
121-123 MAIN STREET,

GENERAL WESTERN AGENTS.

NOTICE TO GOLD MINERS!

SILVER-PLATED AMALGAMATED PLATES

For SAVING GOLD!

IN QUARTZ, GRAVEL, OR PLACER MINES. MADE OF BEST SOFT LAKE SUPERIOR COPPER

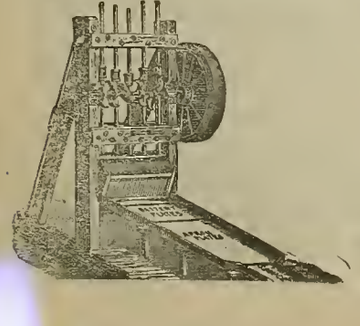
AT REDUCED PRICES.

Our plates are guaranteed, and by actual experience are proved, the best in weight of Silver and durability. Old Mining Plates Replated, Bought, or Gold Separated. THOUSANDS OF ORDERS FILLED.

SAN FRANCISCO NOVELTY, GOLD, SILVER AND NICKEL PLATING WORKS,
108 and 112 First St., San Francisco, Cal.
☞ SEND FOR CIRCULARS.

JUSTINIAN CAIRE, Agent,
521 & 523 Market St., San Francisco,
—DEALER IN—
Assayers' and Mining Material.
—MANUFACTURER OF—
BATTERY SCREENS AND WIRE CLOTH

Agent for HOSKINS'
HYDRO-CARBON ASSAY FURNACES



IMPORTANT TO GOLD MINERS!

SILVER-PLATED AMALGAM PLATES for SAVING GOLD

IN QUARTZ, GRAVEL AND PLACER MINING.

PRICES GREATLY REDUCED.

Only Refined Silver and Best Copper used. Over 3000 Orders filled. Fifteen Medals Awarded. Old Mining Plates can be Replated. Old Plates Bought, or Gold Separated.

These Plates can also be purchased of JOHN TAYLOR & CO., Corner First and Mission Sts

San Francisco Gold, Silver and Nickel Plating Works, 653 & 655 Mission St., San Francisco, Cal., E. G. Denniston, Prop'r.

Our Plates have been used for 20 years. They have proved the best. We adhere strictly to contract in weight of Silver and Copper. SEND FOR CIRCULAR.

AMALGAMATING MACHINERY.

Stamp Mills for Wet or Dry Crushing. Huntington Centrifugal Quartz Mill. Drying Cylinders. Amalgamating Pans, Settlers, Agitators and Concentrators. Retorts, Bullion and Ingot Moulds, Conveyors, Elevators, Bruckners and Howell's Improved White's Roasting Furnaces, Etc.

FRASER & CHALMERS, MINING MACHINERY

CONCENTRATING MACHINERY.

Blake, Oodge and Comet Crushers, Cornish Crushing and Finishing Rolls, Hartz Plunger and Collom Jigs. Frue Vanner & Embrey Concentrators, Evans', Calumet, Collom's and Rittenger's Slime Tables. Trommels, Wire Cloth and Punched Plates. Ore Sample Grinders and Heberle Mills.

IMPROVED CORLISS AND SLIDE VALVE STEAM ENGINES. ❋ BOILERS HORIZONTAL, VERTICAL AND SECTIONAL.

IMPROVED STEAM STAMPS

Hoisting Engines, Safety Cages, Safety Hooks,

Ore Cars, Water & Ore Buckets,

Air Compressors, Rock Drills, Etc.

General Mill and Mining Supplies, Etc.

Sectional Machinery for Mule-Back Transportation.

Pumping Engines and Cornish Pumping Machinery,

Improved Water Jacket

Blast Furnaces for Galena & Copper Ores,

Slag Cars and Pots,

Roots & Baker Pressure Blowers,

Suspended Tramways.

General Offices and Works: FULTON AND UNION STS., CHICAGO, ILL.

Rooms with or without Board.

Free Coach to the House

J. POOLEY.

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, July 31, 1890.

General trade the past week shows a slight increase in the volume of goods going out. The call is setting in from the most remote points, which will be soon followed by near-by distributive places.

Among manufacturers there is nothing new to report. The advance in silver, it is claimed, will be followed at an early day by free orders for mining machinery, for quite a boom in both gold and silver mining is setting in.

The local money market is fairly easy. This, no doubt, is largely due to more confidence felt in the future, and also to the fact that the Government has a large surplus (over $100,000,000), the most of which is to be disbursed in payment of bonds.

MEXICAN DOLLARS—The appreciation in silver has caused freer buying by the Chinese. The market has held strong at 87½@88 cts., with some bolders asking 90 cts.

SILVER — The English and New York markets have gravitated to higher figures, closing to-day (Thursday) at 50⅛d. in London, and $1.10⅛ in New York. In our market the latest sale reported was at $1.09⅝ to a local bank. The Mint has been out of the market for over a week, waiting instructions from Washington. The prevailing opinion is that the price of silver under the new law will be advanced to much higher figures, probably $1.15 and over. Journalistic writers at the East who opposed the position of the MINING AND SCIENTIFIC PRESS on the silver question, now find that events of the past month have verified every statement made by us. Silver does not flow into this country but it is going out at a faster rate than noted for several years past. Our latest European advices warrant the asserlion that the Latin Union is likely to open their mints to the free coinage of silver. But then this may possibly be deferred until the United States Congress passes an Act opening our mints free to silver coinage. Bimetalism is gaining ground in the gold standard countries abroad.

QUICKSILVER—Receipts the past week aggregated 133 flasks. The market is easy at a decline. Exports by sea the past week aggregate 20 flasks to Auckland and 105 flasks to Guaymas.

LIME—Receipts the past week fell off to 297r bbls. The exports by sea aggregate 350 bbls. The market is essentially unchanged. The demand is only fair.

BORAX—Receipts the past week aggregate 1300 ctls. The market is easy, with slight concessions reported obtainable.

CHROME ORE—Shipments to New York show a slight increase. Last week there was shipped by sea 305 690 lbs. to New York.

LEAD—The market does not present any new features deserving of particular mention.

COPPER—Exports by sea the past week aggregate 52 000 matte to New York. The market is exceedingly firm. *Iron Age* reports the New York market on July 24th as follows: The position of the market continues strong and prices are still slowly, but steadily, moving upward. Purchases of 400,000 to 500,000 pounds early in the week under review cleaned up all the Lake Superior that could be obtained at 17c. That price has since been offered and refused for various quantities up to 1,000,000 pounds.

A London cable of July 23d says: Copper has ruled somewhat irregular in price, receding to £57 spot for Merchant bars, and upon purchases of large blocks at that figure subsequently moved up to £57 15s. Speculative holders, fearing a further decline, have realized freely, but the position continues strong.

IRON—Imports the past week aggregate 40 tons from England and 25 tons from New York. The market continues to exhibit a strong tone at full prices. The consumption with us promises to enlarge. Eastern mail advices are favorable to a better market. English cable advices up to July 23d report a strong and advancing market.

COKE—Imports the past week aggregate 662 tons from England. The local market is reported barely steady under free supplies.

COAL—Imports the past week aggregate as follows: Nanaimo, 7516 tons; Port Moody, 1350; Coos Bay, 1150; Seattle, 5000; Tacoma, 5250; Swansea, 1666; Newcastle, N. S. W. 2639. Total, 25,371 tons. The market for all positions is reported strong. Perhaps the only exception that can be taken from this statement is that of late shipments from Australia. The demand with us is quite free, but the supply is ample, but with winter coming on is not in excess of requirements.

Our Agents,

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none out worthy men.

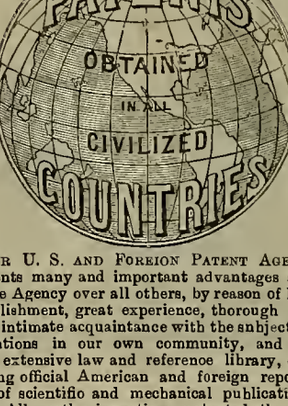
Dewey & Co.'s Scientific Press Patent Agency.



OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

Assessment Notices.

GRAY EAGLE MINING COMPANY—Location of principal place of business, San Francisco, California. Location of Works, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 1st day of July, 1890, an assessment, No. 18, of 6 cents per share, was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, Room 11, No. 303 California Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 4th day of August, 1890, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 25th day of August, 1890, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

A. W. BARROWS, Secretary pro tem.

Office, Room 11, No. 303 California Street, San Francisco, California.

GOVER MINING COMPANY—LOCATION of principal place of business, San Francisco, California. Location of works, near Drytown, Amador county, California.

Notice is hereby given that at a meeting of the Board of Directors held on the 14th day of July, 1890, an assessment (No. 2) of twenty-five cents (25c) per share was levied upon the capital stock of the Corporation, payable immediately to the Secretary, at the office of the Company, 13 and 15 Fremont street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on Wednesday, the 20th day of August, 1890, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on SATURDAY, the 6th day of September, 1890, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

GRAY DEW, Secretary

Office, 13 and 15 Fremont St., San Francisco, California.

DELINQUENT SALE NOTICE.

CARMELO LAND AND COAL COMPANY, Location of principal place of business, San Francisco, California; location of works, Monterey county, California.

Notice—There are delinquent upon the following described stock, on account of Assessment (No. 1) levied on the Fourth day of June, 1890, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Cert.	No. Shares.	Amt.
O'Connell, Annie A	18	100	$50 00
" "	19	100	50 00
" "	20	60	25 00
Green, Wm D	20	150	75 00
Eddy, Ira I	15	100	50 00

And in accordance with law, and an order of the Board of Directors, made on the Fourth day of June, 1890, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the Company, Room 10, No. 415 Montgomery street, San Francisco, California, on SATURDAY, the Ninth (9th) day of August, 1890, at the hour of one o'clock P. M., of said day, to pay said Delinquent Assessment thereon, together with costs of advertising and expenses of sale.

W. T BAGGETT, Secretary.

Office, Room 10, No. 415 Montgomery street, San Francisco, California.

CERTIFICATE OF PARTNERSHIP.

We certify that we constitute a partnership transacting business in the City and County of San Francisco, State of California, and in this State. Its principal place of business is at San Francisco, California. The name is CONNOR & GRANT. The full names and respective places of residence of all its members are signed hereto, and the said copartnership to commence June 1st, 1890.

SAMUEL B. CONNOR, San Francisco, Cal.
ANDREW S. GRANT, San Francisco, Cal.

STATE OF CALIFORNIA, } ss.
City and County of San Francisco, }

On this 12th day of July, in the year one thousand eight hundred and ninety, before me, Geo. T. Knox, a Notary Public in and for the City and County of San Francisco, personally appeared Samuel B. Connor, of said City and County and State, and Andrew S. Grant of the same place, each personally known to me to be the persons whose names are subscribed to, and who executed the within instrument, and they acknowledge to me that they executed the same.

In witness whereof, I have hereunto set my hand, and affixed my Official Seal, at my office, in the City and County of San Francisco, the day and year in this certificate first above written.

[NOTARIAL SEAL.] GEO. T. KNOX, Notary Public.

DIVIDEND NOTICE.

With Diamond Core Drill for Mineral, Oil, or Water, or for Boring Holes for Drainage, Etc.

—AGENTS FOR—

Diamond Drill Machinery and Supplies.

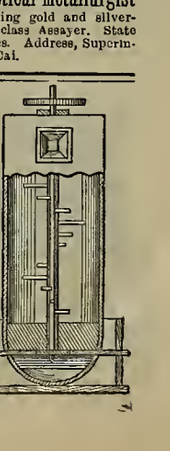
213 Sansome Street, San Francisco, Cal.

Wanted—A Thoroughly Practical Metallurgist

To superintend a large mill working gold and silver-bearing quartz Must be a first-class Assayer. State past experience and give references. Address, Superintendent, Box 2517, San Francisco, Cal.

COMMON SENSE
PULVERIZER AND CONCENTRATOR.

PATENTED DECEMBER 31, 1889.



This is the most practical machine yet discovered for working Gravel, Cement, Clay, etc. By its use you avoid crushing the rocks, which are washed clean, while at the same time it pulverizes the cement and clay and saves the gold, though fine as flour.

You do away with a long line of sluice-boxes and only use about six inches of water. One hundred tons or more of gravel can be worked every twenty-four hours

It consists of an iron cylinder about sixteen feet long, set horizontal, in which a shaft filled with projecting teeth or arms set in spiral form is made to revolve from 150 to 250 revolutions per minute. At the discharge end of the cylinder there is a screen, where the coarse rock is thrown out, while the finer material runs into another cylinder, built in the same way, about twelve feet long, the shaft of which is made to revolve double the speed of the first one, thereby breaking up the finer pieces of cement or clay and freeing the gold, which is deposited in the bottom of the cylinder.

Satisfactory recommendations furnished from practical miners who have seen the machine in actual use. Address

S. K. SNODGRASS,
220 SUTTER STREET, ROOM 13, SAN FRANCISCO, CAL.

SALT LAKE CITY!

ONE OF THE GREAT FIVE.

New York, Chicago, Denver, Salt Lake City and San Francisco.

Midway between Denver and San Francisco, 700 miles from either, with no rivals north to British Columbia or south to Old Mexico, **Salt Lake City** is destined to become one of the great **Overshadowing Commercial Centers** in the chain between New York and San Francisco.

The **recent mighty inflow** of the **best American blood** has **doubled** her population, begun the development of **untold resources**, built up **strong churches** of all leading denominations, created **charming social conditions**, fostered the public school system, **directed municipal improvements** and opened the **most profitable Business Investment, Manufacturing and Mining Opportunities ever presented** by a city that in three years will contain **over 100,000 people**, and before the end of the century several times that number.

MORE MINING CAPITAL NEEDED.

The resources of Utah as a mining region may be shown by the following from the books of the **ONTARIO SILVER MINING COMPANY, Park City, Utah** (near Salt Lake City):

Dividend paid, No. 166, to April 1st, 1890, $10,850,000.00; ore and bullion sold to April 1st, 1890, $24,121,203 13. Incorporated January 1st, 1877. Capital Stock, 150,000 shares; par value of stock, $100.00 per share; market price of stock, $45.00 per share and upward. Average number of men employed, 425. Value of improvements and property (inventory December 31st, 1889), $2,085,854.77.

The Company pays regular monthly dividends of $75,000.00 or 50 cents per share. Utah has numerous dividend payers on a large scale. There are many other mines that are partly developed that promise the richest returns, with sufficient capital. Within three months, coke from our own home coal (Castle Gate) has supplanted foreign coke in our lead smelters.

Salt Lake City is now one of the most delightful homes in the world, with a perfect climate, good society, churches and schools, 50,000 population and growing rapidly. We will be pleased to correspond with mining men and capitalists and point the way to some specially inviting fields. We have many Mining capitalists here, who will cordially meet and aid new men. Our field is large, there is room for all. For illustrated pamphlets, summer tourist rates, and specific information, address

Real Estate Exchange,

SALT LAKE CITY, UTAH.

Rock Drilling and Air Compressing Machinery

BOISE CITY, CAPITAL OF IDAHO.

Metropolis and by provision of Constitution Permanent Capital. Unusual opportunities for investment and business. Capital needed. Mortgages net 10 per cent. Saw mills, brick kilns, woolen mills, iron works wanted. Unlimited water power. Best society, schools, churches. Perfect climate. Stock growers' paradise. **Free Government Land.** Great grain, fruit and vegetable country. Field crops net $25 per acre. Idaho, "Gem of the Mountains," will soon be a State. Third in precious minerals. Output last year, $17,000,000.00. Combine business with pleasure and visit us. Excursion rates.

IDAHO, "GEM OF THE MOUNTAINS."

Idaho's rapid increase in late years in mineral production is due to the scientific methods formed by capital and long experience. There is large opportunity throughout the mining districts of Idaho to develop mines with almost the certainty of large profits. Gold bullion is cashed at the Government assay office in Boise City. At the same time no mining field offers more attractive inducements to the hardy miner whose capital lies chiefly in his experience and in his pick. Full and complete information concerning Idaho mines will be mailed on application.

IRRIGATING CANALS.

Another great opportunity for capital in Idaho is in large irrigation enterprises. Projects are on foot to reclaim several hundred thousand acres, but there is room for many other such projects. Idaho has abundance of water, and the profits of irrigation are large and sure.

PACIFIC ROLLING MILL CO.,
.....MANUFACTURERS OF.....
Cast Steel Castings and Steel Forgings
UP TO 20,000 LBS. WEIGHT.

True to pattern and superior in strength, toughness and durability to Cast or Wrought Iron in any position or for any service.

GEARINGS, SHOES, DIES, CAMS, TAPPETS, PISTON-HEADS, RAILROAD and MACHINERY CASTINGS of Every Description.

—ALSO—

HOMOGENEOUS STEEL, SOFT and DUCTILE, SUPERIOR TO IRON FOR LOCOMOTIVE AND MARINE FORGINGS.

ALSO Steel Rods, from ¼ to 3 inch diameter and Flats from 1 to 8 inch. Angles, Tees, Channels and other shape Steel Wagon, Buggy, and Truck Tires, Plow Steel; Machinery and Special Shape Steel to size and lengths **STEEL RAILS** from 12 to 45 pounds per yard. ALSO, **Railroad and Merchant Iron,** Rolled Beams, Angle, Channel, and T Iron, Bridge and Machine Bolts, Lag Screws, Nuts, Washers, Ship and Boat Spikes; Steamboat Shafts, Cranks, Pistons, Connecting Rods, etc. Car and Locomotive Axles and Frames, and Iron Forgings of all kinds, Iron and Steel Bridge and Roof Work a Specialty.

HIGHEST PRICE PAID FOR SCRAP IRON AND STEEL.

☞ Orders will have prompt attention. Send for Catalogues. Address

TUSTIN'S PULVERIZER.

—MANUFACTURERS OF—

MARINE ENGINES AND BOILERS.—Propeller Engines, either High Pressure or Compound, Stern or Side-wheel Engines.

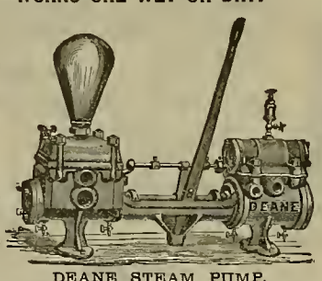
MINING MACHINERY.—Hoisting Engines and Works, Cages, Ore Buckets, Ore Cars, Pumping Engines and Pumps, Water Buckets, Pump Columns, Air Compressors, Air Receivers, Air Pipes.

MILL MACHINERY.—Batteries for Dry or Wet Crushing, Amalgamating Pans, Settlers, Furnaces, Retorts, Concentrators, Ore Feeders, Rock Breakers, Furnaces for Reducing Ores, Water Jackets, etc.

MISCELLANEOUS MACHINERY.—Flour Mill Machinery, Saw Mill Engines and Boilers, Dredging Machinery, Powder Mill Machinery, Water Wheels.

Tustin's Pulverizer
WORKS ORE WET OR DRY.

ENGINES AND BOILERS
OF ALL KINDS,
Either for use on Steamboats or for use on Land.
Water Pipe, Pump or Air Columns, Fish Tanks for Salmon Canneries
OF EVERY DESCRIPTION.
Boiler Repairs Promptly attended to and at very moderate rates.
AGENTS FOR THE PACIFIC COAST FOR THE
Deane Steam Pump.



SPECIALTIES:
Corliss Engines and Tustin Ore Pulverizers. DEANE STEAM PUMP.
Agents and Manufacturers of the Llewellyn Feed Water Purifier and Heater.

THE GIANT POWDER COMPANY
Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as
The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,
Of Different Strengths as Required.
NOBEL'S EXPLOSIVE GELATINE," which contains **94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite** and even Safer in Handling.

JUDSON POWDER IMPROVED.
FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

BANDMANN, NIELSEN & CO.,
CAPS and FUSE for Sale GENERAL AGENTS, SAN FRANCISCO CAL.

QUARTZ SCREENS
A specialty. Round, slot or burred slot holes. Genuine Russia Iron, Homogeneous Steel, Cast Steel or American planished Iron.
Zinc, Copper or Brass Screens for all purposes. California Perforating Screen Co., 145 & 147 Beale St., S. F.

COAL MINES OF THE WESTERN COAST.
A few copies of this work, the only one ever published treating of Pacific Coast Coal Mining, have been obtained, and are for sale at this office for $2.50 per copy. It was written by W. A. Goodyear, Mining and Civil Engineer, formerly of the California State Geological Survey.

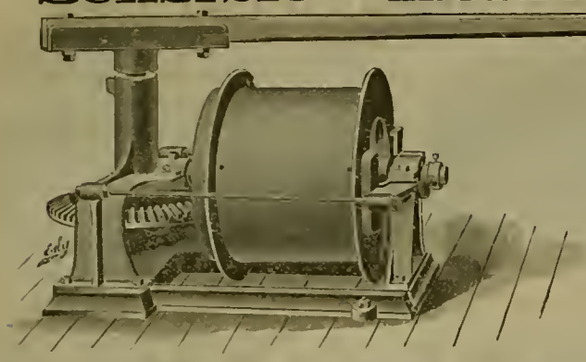
"Sensible" Horse Power Hoisting Whims.



These Hoisting Whims are built entirely of Iron and Steel, mounted on a heavy base plate, and, consequently, are very durable and cannot be affected by extremes of either cold or heat or climatic influences.

The hoisting drum is completely under the control of the person in charge of the hoisting or lowering through the shaft of the mine.

As the drum is entirely independent from the driving gears, the operations of hoisting, dumping bucket and lowering can be performed with the horse in constant motion, a feature not possessed by any other horse hoist in the market, and one that greatly increases their capacity by avoiding the loss of time due to stopping and starting the horse.

They are very light and compact, and can be packed for transportation by mules. Their cost of erection is very slight; two men, in half a day, being able to put one in place, ready for work.

With each Whim, working drawings are furnished showing in detail the proper construction of Gallows Frame and foundation for Hoisting Whim.

We carry in stock the following sizes:

No. 1.—Capacity with One Horse and Single Line, 800 pounds, 75 Feet per Minute.

No. 2.—Capacity with One Horse and Single Line, 500 pounds, 125 Feet per Minute.

Weight of machine, 1200 pounds. Total shipping weight, including Sweep, Levers and Sheaves, 1400 pounds.

NO DANGER.
Horizontal, Upright and Marine Vapor Engines and Launches.
Three fourths to Fifteen Horsepower. From $175 to $1200.
Send for Our Large Illustrated Catalogue.

GEORGE HAAS, 824 Market St., Phelan Building, } SAN FRANCISCO, Feb. 21, 1890. }

REGAN VAPOR ENGINE CO.—Gentlemen: The 2 H. P. Engine you put up in our factory last November, has given satisfaction beyond my expectations. It does my work better than than those two Electric Motors did, with scarcely any expense for gas. I paid the Motor Company $25 per month for power, while the Vapor Engine has cost me but $2 per month so far. But, be it understood, I have not used the Engine as much as in summer, but the cost of motor would have been all the same, making a saving of $69 in three months. I am satisfied the Engine will pay for itself in less than two years. I use it for freezing cream, run three fans, coconaut grater, etc.

Yours truly, GEO. HAAS.

Regan Vapor Launches

The uses for small steamboats and launches are innumerable; they are convenient and serviceable for transportation, and are a source of pleasure for those who are fond of sailing. But many have been deterred from purchasing such boats, because of the trouble and inconvenience of using coal, and the necessity of obtaining a Government license, engineer, etc. Our motor does away with these objections. The small space taken up by our engine in the boat **gives more room**; the boat will seat **twice** as many persons as one the same size fitted up with a steam engine. It takes only **two minutes to get under headway**, and can be stopped when running at full speed within the length of the boat, the reverse motion being instantaneous and effective. We carry in stock six regular sizes of hulls, from 18 to 33 feet in length, our models being the best that can be obtained, and built in the strongest and most substantial manner by Thos. Kane & Co., Racine, Wis.

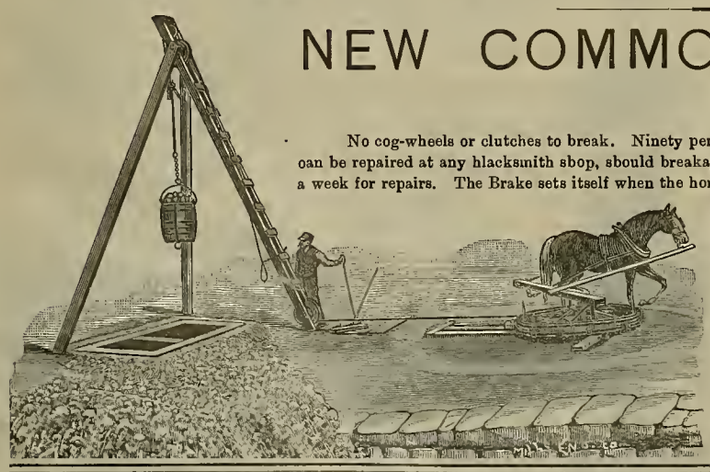
NEW COMMON SENSE STEEL WHIM.

All Complete for $150.



No cog-wheels or clutches to break. Ninety per cent of this Whim is wrought iron and steel, and will spring or bend before breaking, and besides can be repaired at any blacksmith shop, should breakage occur, thus obviating the necessity of sending away hundreds of miles sometimes, and waiting a week for repairs. The Brake sets itself when the horse stops or anything gives way.

It can be packed anywhere a jack can go, the heaviest piece weighing but 100 pounds; total weight, 650 pounds. The sweep can be thrown out or in gear at any time, and the bucket hoisted, dumped or lowered while the horse is in motion. It is just as safe and reliable as an engine, and can be handled as readily, and is just the thing to open up a mine and make it pay. Spending thousands of dollars in fine machinery and shaft houses has "busted" many a company. Buy a COMMON SENSE WHIM, and when you have got more ore than our Whim will hoist, then it is time to buy an engine, not before. It will save you thousands of dollars if your mine should not pay. Being all iron except the sweep, it will not rot, warp, twist, or get out of true. Being wrought iron, it will not break in transportation. We also make TWO, FOUR and EIGHT Horse Power Whims, Derrick Whims, and Building Hoists, Ore Buckets, and everything pertaining to Horse Power Hoisting. State for what purpose, and at what place you want to use it.

☞ Come and see one at our works in operation, or send for circular.

Mineral, Not Agricultural.

An Important Decision For California Miners.

In the United States Circuit Court in this city, on Wednesday, a verdict for the defendant was rendered in the case of George H. Francoeur against Oscar Newhouse, an action in ejectment involving the title to the Eagle Bird mine, situated near the town of Washington, in Nevada county. The case has been on trial for three weeks, with the plaintiff represented by ex-Attorney General Hart, assisted by William Singer, attorney for the land department of the Central Pacific Railroad, and the defendant by Reinstein & Eisner and J. M. Sewell.

The plaintiff claimed the land under a deed issued to him by the Central Pacific Railroad Co. in February, 1890. On July 1, 1862, the railroad company received a grant from the Government embracing all the odd sections within ten miles of either side of their road, which excepted all mineral lands. By the United States Land Department it has ever since been considered an open question whether land can be considered mineral land unless a patent has been issued, or whether it must be entered on the books like any ordinary claim.

The defendant, Newhouse, in this case obtained a mining patent in 1887, on the strength of which he based his claim to possession. The Court instructed the jury that all such land as was readily ascertainable as mineral land in 1862, or at the date of definite location of the railroad, must be considered excepted from the grant, and the verdict found for the defendant was principally based on that issue, ignoring the plea of the plaintiff to the effect that the railroad company is entitled to all lands which were not known to contain minerals in July, 1862.

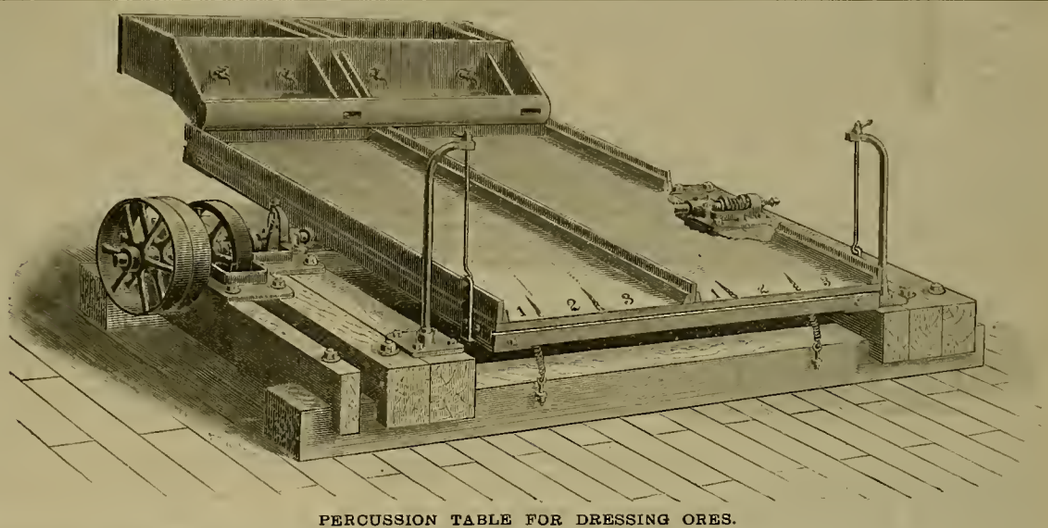
For the plaintiff it was maintained that the railroad grant of July 1, 1862, gave to the company a clear title to all odd sections of land, unless they were known to be mineral lands, and from which mineral in paying quantities was being taken previous to July 1, 1862.

This decision will be hailed with joy by all mine-owners on odd sections along the railroad. In the Sacramento land district alone, there are 750 patented claims located on odd sections, and the present owners of them have for months been watching the Francoeur-Newhouse case with much anxiety as to the final outcome. Many valuable mines in all parts of the State are situated likewise, and there is no doubt that the suit decided Wednesday was only brought as a test case, and that the railroad people were really the plaintiffs. Had the decision been the other way, a large number of similar complaints against other mine-owners would have been entered.

The jury find that the land was known to bear mineral when located by the R. R. Co., and should not have been listed as agricultural land.

This case is not only important to California, but to Idaho and Montana. In the latter State the Northern Pacific Co. is claiming large tracts of land on which mines have been worked for years. Yet it is claimed as agricultural.

A decision the reverse of that which has been given would have been a sad blow to the mining interests of this State. Not only quartz mines were in question, but large tracts of drift mining country as well. The mining community is to be congratulated on the results of this test case.



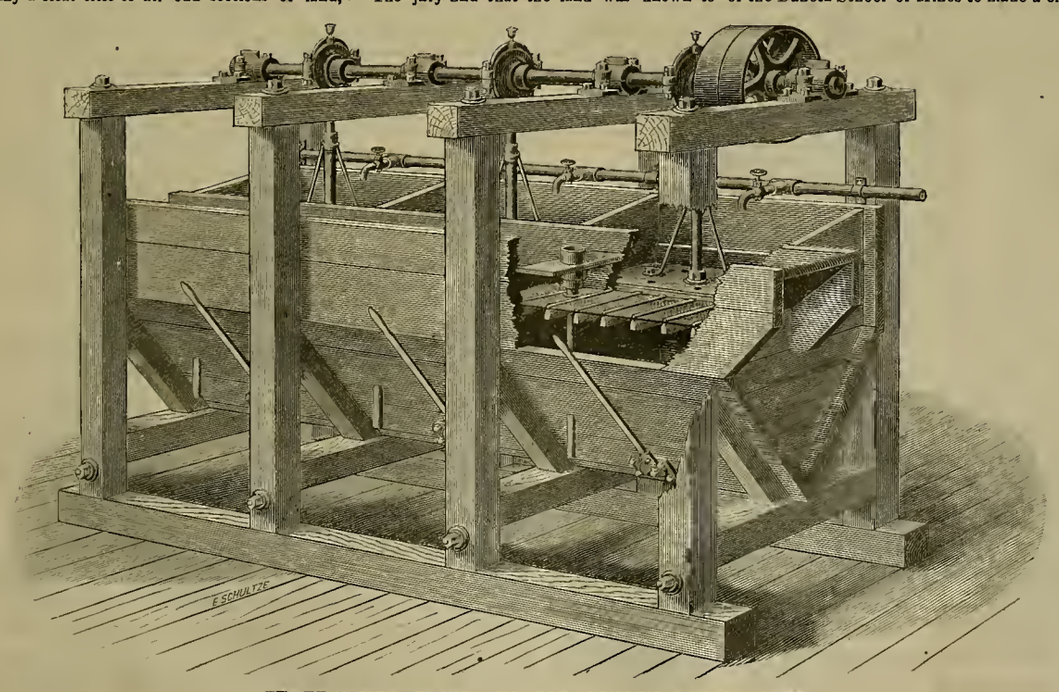
PERCUSSION TABLE FOR DRESSING ORES.

Dakota School of Mines.—The State Board of Regents recommended to the trustees of the Dakota School of Mines to make a clean sweep of the old faculty, and the trustees did it. The old faculty had become more or less involved in a sectional or factional fight. The object of the Regents was to make the school a State and not a local institution.

Jigs and Percussion Tables.

The accompanying cut shows a three-compartment jig with part of the side removed to show the screen and method of securing it in place. The ore is fed in the spout shown on the end of the jig to the first screen, and by the action of the loosely-fitting plunger, worked by an eccentric secured to the shaft on the top of the jig-frame, the water washes the lighter and coarser material over to the next screen, and so on until it has reached the last one, thus making a very complete concentration. The eccentrics are made of cast iron and generally keyed to the shaft but sometimes secured by set screws. The eccentric rods that operate the plunger are of wrought iron and have side braces to prevent twisting or bending. The boxes are babbitted and tight and loose pulleys are furnished. Cast-iron discharge gates are bolted to the side at the bottom as shown. The Union Iron Works of this city, who make this jig, are prepared to build jigs of any number of compartments that may be required.

The other engraving shows a percussion table of the kind extensively used in Germany in ore concentration, but not so common in this country. This is a common type of table and one that is cheap to build. It is hung by the bolts connected to the upright stands that are bolted to the timbers. This gives it a free motion, and by a peculiar mechanical device the table is pushed to one side and suddenly released and sent back by means of a spring on the opposite side. They are furnished with a tight and loose pulley as shown.



THREE-COMPARTMENT JIG FOR CONCENTRATING ORES.

James Whitlatch, a mining man well known all over the coast, committed suicide in this city last week. The cause was despondency due to financial troubles and poverty. He was the locator of the famous Whitlatch-Union mine, Montana, and has made and lost half a dozen fortunes since he began his mining career in California. Deceased was about 48 years of age.

CORRESPONDENCE

we admit, unindorsed, opinions of correspondents - EDS.

The Gold Belt of Northern California.

Ancient River Chan els and Gravel Deposits.

NUMBER IX

[Written for the MINING AND SCIENTIFIC PRESS by JAMES F. TALBOTT, Blue Canyon, Placer Co.]

Coaree Gold.

At Shady Run in the old Blue Bluff claims, a lead of coarse gold in apots has been followed several hundred feet back into the flat; nuggets weighing from 1 ounce to 20 and 30 ounces have been found in this lead. To the east of this flat or basin is a narrow outlet into Blue canyon. From this point down the canyon a mile or two, some extremely rich crevices were found, containing coarse gold of the same kind as that on the hill. At about a certain distance down the canyon the coarse gold gives out, and as in other places the richness diminishes. The canyon presents the same appearance for several miles above, but no pay has ever been found above this outlet.

The same conditons are observed on the Nevada ridge. From a rich deposit in Bear river, at the month of a small ravine, the pay was followed up the ravine into a richer deposit in the hill at Little York. The first discovery of hill diggings in California was at Nevada City, where the pay in a rich ravine was followed from Deer creek up into the richest and most extensive deposit of this character ever found in California or any other place—the famous "Old Coyote" lead. A peculiarity observed in regard to these

Rich Shallow Depoelte

On the hills is that they invariably face to the south or west. This is accounted for from the general slope of the country being in that direction, thereby giving free outlet; while a break, with an outlet to the east or north, is running against the elevation of the country in these directions and is soon blocked up; hence no extensive or rich deposits are found in these directions from the source; whereas, to the south and west the outlets are unobstructed, and the gold is concentrated in those places, under the conditions previously indicated.

In some localities very rich small deposits have been found, where no trace of the source can be observed. We can account for this from the fact that the immense deposit of lava, immediately overlying the main river-beds, and its solid indestructible character has resisted the action of modern erosion, while the greater portion of their lateral tributaries and canyons, being free of lava, have been swept away and entirely obliterated, and a portion of the gold that was in them has been deposited in these isolated spots, where no traces of its source have been left.

In some localities in the upper part of the gold belt some considerable sections of those tributaries still remain. On the Middle Fork Divide several are observed, as at Deadwood, Last Chance and other points. But as this is near the line of the main lava flow, the most of them are capped with lava.

On the southern slope of the North Fork Divide is one of quite and considerable extent at Lost Camp. This is an isolated section, situated about three miles a little north of east from Shady Run, and a mile and a half directly south from the town of Blue Canyon. It is about three-quarters of a mile in length, running east and west through a low sag in the ridge between the north branch of the North Fork and Blue Canyon, and is abruptly cut off at either end by a deep gorge. Between it and the Shady Run lava-capped ridge to the north, a high range of bedrock country intervenes, south of which no trace of lava is seen. On the south, toward the North Fork, is a high rim-rock. Immediately to the east the deep canyons and branches of the North Fork have swept the entire channel away for several miles in that direction, and apparently to near its source in the vicinity of Monumental, Barnett and Wilmot canyons, where considerable gravel deposits still remain. The upper portion of the channel in this section is considerably broken up, and the bottom deposit somewhat irregular. The top formation is an irregular mass of material from the surrounding country, composed chiefly of float quartz and bedrock but slightly worn, intermixed throughout with a body of light yellow clay. This is evidently from

An Immense Slide

Coming from the high bedrock range to the northeast, which probably blocked up the channel here and prevented this section from being carried away. At the lower or west end, from where it breaks off into Blue canyon, the channel is about 50 feet wide and well defined. The bedrock is hard and water-worn on the high points and pot-holes. The bottom stratum, in which the pay is found, is a solid compact body of gravel and bowlders from 5 to 10 feet in depth, principally quartz. The top formation is about the same as that at the east end, only more worn and rounded, with less clay in it, and is evidently a wash from the slide above, which has filled in above the bottom deposit to the depth of 50 feet and carried the lighter material on to the south rim a quarter of a mile beyond, where, on the bedrock points, a few feet in depth, a barren deposit of fine gravel intermixed with the yellow clay, is left.

An Isolated Section of Channel.

Here then, is an isolated section of a small well-defined channel, which unmistakably belonged to the ancient system. To the east an apparent connection can be made with gravel deposits indicating its source, but in no other direction can a vestige of the channel be discovered. To the north and northeast is a high bedrock country—on the south a high rim and two high bedrock ridges intervene between it and the Middle Fork Divide. To the west is the high rim of the channel in the Shady Run ridge, heretofore described.

The only course possible for it, then, is to the southwest — the natural course of all, ancient and modern. The natural conclusion is that this one-time channel, free from lava, ran about parallel with that in the Shady Run ridge, down to or below Bogus Point, where it formed a junction with the main one, and that the floods from the combined displaced waters of both divides rushed into this tributary and carried every trace of its existence away as far up as Lost Camp, cutting out the deep gorge of Blue canyon and other branches of the North Fork, when all of the forces were united and cut out the famous gorge of Giant's Gap, and below Bogus Point swept away every vestige of the main ancient channel of the North Fork divide.

Relatione Between Different Localities

This is a wide and deep subject, and most all of the articles heretofore written in regard to it appear to have been by some casual writer, visiting the rich and well-developed localities, unacquainted with the general character of the surrounding country and the existing relations between different localities. As a consequence those articles only reflect the narrow views of certain individuals, whose observations for the past twenty years, probably, have not extended beyond the vision of the principal saloons of the place, and who see in the deep gravel deposit of their locality, the main ancient river channel—the "Hub" of all the mines in the country, particularly if there is "blue gravel" in it.

It is not intended in this article to give any new information in regard to the mines on the Middle Fork Divide, but, for the purpose of comparison, to call attention to certain facts and to certain conditions observed on the surface that indicate to a degree of certainty the conditions of the underlying formation, which is practically demonstrated here by actual workings. Those surface indications have heretofore been outlined to some extent, and the underlying formation is brought into full view by extensive developments. The mud (cement) and lava flow inside the rim-rock walls has been traced on the surface for a long distance in a definite course, and, at different points, many miles apart. On this course deep shafts have been sunk and long tunnels have been run through the rim-rock, and the underlying formation of bowlders and gravel are found, containing the rich deposits of gold. Only where breaks occur through the rim to a certain depth are extensive and rich gravel deposits found outside the rim.

(To be Continued.)

The Accident at Hayden Hill Mines.

EDITORS PRESS:—A fearful accident happened at the Hayden Hill mines on July 24th, when two men lost their lives in the Eclipse mine.

Frank Auble and William Dunbar were down in their mine working, when a fire broke out in the buildings over the shaft. The fire is supposed to have started in the blacksmith shop close to the whim house. The house over the shaft taking fire, gave the men in the mine no possible chance for escape.

There being no one on the surface to give the alarm, the buildings were nearly consumed before being discovered by other miners on the Hill. The fire was soon extinguished after being discovered, but had meantime burned down the shaft the depth of two sets of timbers.

After the fire was extinguished, men were let down the shaft to learn the fate of Auble and Dunbar, but none could stand the suffocating atmosphere. Mr. L. Richie was the first to be let down the shaft and had to be hoisted up, being nearly suffocated.

About 8 P. M. word was telephoned to Mr. Charles Auble at Adin, brother of Frank Auble, and he immediately started for the Hill. Word was also sent to another brother, G. Auble, who resides seven miles from Adin.

Every attempt to enter the mines was fruitless until the next day, July 25th, when two of the Auble brothers succeeded in getting down to the 40 foot level. There in the drift about 60 feet from the main shaft were found the two dead miners. Mr. G. Auble being a man of courage, he succeeded in getting the lifeless remains out of the mine with the help of others. Both men belonged to the Odd Fellows' Society and were buried by the Order. There was a large procession of sympathizing friends. Mr. William Dunbar leaves a widow and two small children to mourn his sad fate. Mr. Auble leaves two children, his wife having died some years ago.

Both men have many sympathizing friends here. H. KELLEY.

Adin, Modoc Co., July 26, 1890.

San Bernardino County.

Its Mineral and Other Resources.

NUMBER V.

[Written for the PRESS by JAMES H. CROSSMAN.]

Calico Mountain

Calico mountain contains a species of coarse granite; hornblende and andesite also occur, but the nomenclature of these rocks, their origin or mode of occurrence does not interest the prospector, miner, or mine proprietor. He only seeks to know the size of the vein, the assay value of the ore and its character, whether free or base, copper, gold or silver. He wants to know if it goes in the deep and that the pay chute has sufficient longitudinal proportions. The answer satisfactory, the miner is content.

To the geologist and student, mineralogist and metallurgist, Calico mountain is a field of great interest. He can find here not only a great many varieties of rock, but evidences of intense volcanic activity, and many of the ores of silver, gold, copper and iron. He can also find typical specimens of all classes of veins known to exist. It is a free and open school for the student in which to take lessons in practical mining and milling preferable to either Freiburg or Berlin. There he can only obtain a theoretical knowledge of the art, but in Calico he combines theory with practice. Let him win his spurs and diploma from the rocky structure of some one of the many deep-seated fissures that abound in this region; learn the length of the chimney or chutes of ore; learn the difference between a "fissure" vein, a "blanket deposit," or a "gash" vein; learn how to pitch his hole in order to throw the most rock for a given amount of explosive material; learn the use of the tools of the craft, how to make a survey and an assay, how to manipulate the machinery in use. Then let him go to the mill and reduction works and learn the secrets of the millman's art. He will be then better qualified to judge of the character of a mineral vein or deposits than many who have graduated with all the honors and received their diplomas from the professors of the celebrated mining colleges of Germany and elsewhere. At least he will know the difference between a "true fissure vein" and a "crack." The latter term has been used by one of our prominent mining and scientific lights in his pronounced classification of all of the mineral-bearing veins that occur in the Calico mountain, which, to use his own classical expression, he dubs as "cracks."

In this connection I would state that it is not my object or intention to decry science or scientific attainments that have been acquired in the celebrated schools referred to, but theoretical knowledge without practical work in the field is of but little benefit.

The Ore-Bearing Material

That forms the gangue of the Calico veins consists principally of heavy spar, quartz, tufa, sandstone and indurated mud, the latter evidently ejected from some deep-seated source as a volcanic product, and often found rich in the ores of silver.

The most notable, extensively worked and best defined veins on the Calico mountain are the King and Waterloo. They carry smooth and well-defined inclining walls showing "slickensides" (gouge) for long distances. Several of the veins on Calico mountain cut the formation at varying angles and so far as exploited, show no signs of weakening as "they go to the deep." Certainly no surface crack or superficial deposits could have produced these results. If these general characteristics do not constitute a "true fissure," not a "crack," my 42 years' experience from Cerro Pasco, Peru, to the Comstock of Virginia City, goes for naught. On the northerly flank of the Calico mountain an important and interesting bed or measure of crystalline borates occur, known as "colmanite," of an unusual high tenor in its boracic product. This seam or measure carries transparent crystals of extraordinary beauty and in great quantities. They are sought for and highly prized by all of the scientific institutions in the world. This mine is being extensively worked and its product daily shipped to San Francisco via Daggett for refining. Details of not only this but of other mines in the county will be described later under their appropriate head.

Avawatz Mountain.

Course northwesterly and southeasterly, 25 miles in length by 20 wide. Its greatest elevation is 6500 feet, aneroid reading. This mountain is situated about 60 miles in an air line nearly due north from Calico. The formation, mineralogical structure and character of its ores resemble in a marked degree those of the Ord Mountain which I have previously described. Kaolin and foliated talc are found in great abundance. Near the summit of the highest peaks veins of gold, silver, copper and lead occur. About 30 miles northeasterly from Cave Wells, which are located about 2½ miles easterly from the summit of the Avawatz range on the road leading from Daggett to the Amargosa Borax works and Resting Springs mine, a high, gloomy, desolate range of mountains is seen, known as the

Kingston Range.

This is the first range of mountains encountered after crossing the southerly rim of the Death Valley basin. It is marked by high and almost vertical peaks—the highest of which is Kingston Peak, which is 8000 feet above the level of the sea and forms a prominent landmark. The range, peak and spring at its base derive their names from a man by the name of Kingston who formerly had a contract for and carried the mail between Salt Lake City and San Bernardino county, when life on the desert held an uncertain tenure, owing to Indian raids. On its northerly end large deposits of argentiferous galena occur. This mountain, including Good Spring mountain, is 12 miles long by six in width. Course due north and south. Its axis is granitic. On its westerly bank a secondary granitic rock occurs and on the east a lime belt of great strength and persistence is seen. About six miles northerly from the above named peak is a low range apparently an off-shoot from the main Kingston mountain. The extensive argentiferous lead deposits surrounding Resting Springs occur on the northerly extremity of the main range. At this point the mountain is shattered and broken until finally, losing its integrity in Ash meadows 25 miles distant, it altogether disappears. The same formation extends in a southerly direction through Good and Resting Springs.

Good Spring Mountain

Lies southeast of Kingston and in line with it. The formation is granite and a stratified limestone and a lime schist much broken by volcanic action. Metalliferous veins of quartz occur, carrying the ores of lead, silver and gold. This mountain is a prolongation of Kingston range.

Traveling in a southeasterly course from Tacopa a distance of about 40 miles, we reach

Clark Mountain.

Its course is northerly and southerly, and it is about 20 miles long by 10 wide. It reaches its greatest elevation on its southerly end, where Clark's Peak rises to a hight of 4200 feet above the level of the sea. This peak is a noticeable landmark that can be seen from almost any elevated position in the desert for a long distance. Its most northern point terminates in Nye county, Nevada. This mountain range is celebrated for its ores of silver, copper and lead—the first of extraordinary richness and known as a silver-copper glance.

East of the last-named mountain range, crossing 20 miles of a desert whose only vegetable product is the cactus and an occasional tuft of bunch-grass, we reach the

New York Range.

Its course is north and south; it is 20 miles long by from 4 to 6 in width; elevation, 2200 feet. Through this mountain there courses longitudinally important mineral-bearing veins that crop boldly, their crests exposed for long distances. The ores are of copper, silver and lead. Thence easterly for a distance of 20 miles, we reach a low mountain range that borders on and forms the westerly rim of the Colorado river, which is known as the

Colorado Range.

This range extends in a southerly direction to a point near the boundary line of San Diego. The range contains several important mineral districts, carrying the ores of gold, silver, copper and lead, particularly below The Needles. In the more northern portion of the county, adjoining the Nevada State line,

The Yellow Pine Range

Occurs. Its trend is from northwest to southeast, with Charleston Peak its highest point, reaching an elevation of 10,844 feet. This is snow-clad the most of the year, particularly so on its northerly exposure. A broad belt of lime courses longitudinally through this range which contains fossil marine shells. This mountain, at an elevation of from 4000 to 6000 feet, is covered by an important belt of pine timber which is largely owned and controlled by Mr. N. Clark, who has erected a sawmill on the belt which he utilizes whenever there is a demand for lumber. The best timbered portion of the range enters Nevada from 10 to 20 miles northeast of the California State line. This belt of timber lies principally to the east of Charleston Peak, which is distant 150 miles northeast from the town of Daggett. The range extends from Providence mountain on the south to Pahranagat valley on the north. The valley is well watered and noted for the fertility of its soil, producing large crops of all of the vegetable products of the temperate zone. It is extensively cultivated by enterprising farmers. Stock find good pasturage in the foothills of the valley.

Returning to Clark's mountain again, we travel due south for a distance of 42 miles and reach the town of Providence on the easterly flank of the central portion of

Providence Mountain.

The course or trend of this mountain is northwest and southeast. It has a greater longitudinal extent than any mountain range in San Bernardino county north of the San Bernardino range of mountains. Its extreme length, inclusive of Old Dad on the south, from which it is only divided by a low pass, and the Macedonia and New York ranges on the north (connected the entire distance by low ranges of hills), may be estimated as follows:

Old Dad, ten miles long by eight miles wide; Providence proper, 20 miles long by eight miles wide; Macedonia mountain, including a low connecting range of hills 42 miles long by four wide in its widest place; New York range, ten miles long by four wide, forming in the aggregate a mountain range 82 miles in length by from four to ten miles in width.

The central portion of this mountain is Providence proper, and contains many marked features of great interest to both miner and

scientist. To the first its attractive features consist in its great store of mineral wealth, the details of which will be more fully described under the head of "Mineral Districts and their Mines." The scientist will probably be more interested in its structural formation and geological character. It is bounded on the east by an extensive valley which is from 30 to 40 miles in width and more than 100 miles in length.

Volcanic Structure.

This valley is dotted with volcanic cones that at no remote period in the world's history poured forth mud and broken rocky fragments. In the near vicinity, conical peaks, with their lava-covered flanks and basalt capped summits, form tablelands of considerable extent, and stretching away to the west, furnish evidence of the enormous mass of molten material ejected from these vents. This period of volcanic activity was, in all probability, contemporaneous with that which destroyed the integrity of Calico mountain and vicinity. Providence mountain proper, looking from the east at a point near Fenner on the line of the Atlantic & Pacific R. R., has the appearance of a sharp, serrated ridge, with vertical cliffs and steep canyons. It is composed of many varieties of rock, much metamorphosed and showing the effects of powerful heat, with dykes of eruptive rock of from 200 to 400 feet in width. The formation, however, is more regular and less disturbed than one would expect.

Ore-Bearing Veins.

Its central core is evidently granite, while on both the easterly and westerly flanks broad belts of limestone occur from two to three miles in width, usually dolomitic, alternating with bands of porphyry, secondary granite, quartzite and talcose slates, inclosing numerous strong veins of quartz and spar on their contact lines. These are persistent and course for miles uninterruptedly, forming the metalliferous domain of the district and range. The ore-bearing veins often expand into large chambers, and in places contract to a seam, but are continuous on their line of strike. A noticeable feature where expansions take place is that large feeders or spurs fall in, and at their intersection the ores are invariably rich. The writer followed this belt for a distance of eight miles without noticing a break or dislocation. This occurs at an elevation of 4000 feet above the sea level.

On the easterly flank of the mountain the ores bear silver-lead and silver in the form of a chloride, usually accompanied by zinc either as a sulphide or as an oxide. On the westerly slope of the range, from three to six miles distant at a right angle, the ores carry gold, silver and lead. The want of water and fuel seems to have been the principal obstacle in the way of making this a large and productive mining camp. To obviate this difficulty and supply this much-needed want, extensive reservoirs should be constructed at suitable places to conserve the waters that run to waste, and artesian water should be sought for in the valley. The mountain is not destitute of a limited supply of the aqueous fluid. Springs of pure limpid water gush forth from several places on the flanks.

Old Dad

Is a mountain 15 miles long and 10 wide, and on the south is the dominant peak of the Providence mountain range. Its elevation is 6300 feet above the level of the sea (aneroid readings) and in the winter months it is clad with a mantle of snow. The dividing line between it and the Providence mountain proper is a low pass through which a road leads to the interior desert region of the Death Valley country. Old Dad is situated 25 miles westerly from Danby and 40 miles from the base of Old Woman's mountain, which lies in an easterly direction. Its formation is similar to that of Providence and contains metalliferous veins of the precious metal. Its extreme southerly point is within six miles of Danby, a station on the A. & P. R. R.

The Rock Spring Range

Courses southwest and northeast and at a right angle with the Providence range, bisecting it in a northerly direction from Providence proper. It is entirely composed of granite of an older formation than any that I have seen in the desert. It contains numerous springs of water but no minerals.

The Old Woman's Mountain

Lies at an elevation of 4500 feet, in an easterly direction. Its course is northeast and southwest, 30 miles long and 20 in width. It derives its name from a pinnacle of granite that stands alone on the summit of the ridge in bold relief against the horizon. This solitary figure rises to a hight of from 30 to 40 feet, and at the distance of a few miles resembles in a marked degree the statue of an aged human being of the feminine persuasion dressed in fashionable attire.

The resemblance is so striking that the observer can scarcely believe that it is not a work of art executed by some vagrant artistic sculptor who had strayed into these desert regions and left evidences of his skill. This mountain is 30 miles in length by 20 in width. Its axis is a secondary granite with a northerly and southerly trend. The mountain is bisected by a strong belt of magnesian limestone accompanied by calcareous shale and magnesian and talcose slates which carry strong veins of quartz charged with the ores of lead and silver. In the granite adjoining the veins are small but well defined. The ores are of copper and gold. The nearest point to rail (the A. & P.) is eight miles north at Danby, to which a trail has been built to pack ores from the mines. The Clipper mountain range lies south and west of the A. & P. R. R. It is 10 miles long by five wide; its greatest elevation is 7000 feet.

Sheep Mountain

Lies in a southwesterly direction from Danby, distant eight miles. Its formation is granite on the west and porphyry on its easterly flank. Lying parallel and adjoining is a belt of dolomitic limestone from 50 to 250 feet in width in which and on its line of contact, a large bed of specular iron occurs. This is the lime belt that crosses and enters the Old Woman's mountain. This mountain on its westerly flank shows evidence of volcanic activity; a number of large mud cones are seen at its base.

Sheep Mountain.

As seen in the distance, is one of considerable length, but rising to no great hight. It lies parallel with the course of the Atlantic & Pacific railroad, forming the southerly rim of that portion of the desert region through which the road passes. It is reported to contain metalliferous veins.

Iron Mountain

Courses easterly and westerly, and is ten miles long by 3½ wide. It is nearly due south from Old Woman's mountain, 57 miles southeast from Danby and 42 miles westerly from the Colorado river. It contains gold, iron, and an immense deposit of copper. The latter is reported to be of a high tenor, assaying 38 per cent copper, and from $20 to $75 gold per ton.

In writing the foregoing articles on the mountain ranges of the desert regions, the writer has confined himself as closely as possible to the geological features of the several mountain ranges, with but little reference to its detailed mineralogical character which will be presented under the head of "Mineral Districts." That the desert region contains immense stores of mineral wealth no intelligent man who has visited these sections can question. Want of cheap transportation, fuel, which the railroad can supply, water, which can be drawn from subterranean sources by the assistance of artesian wells and artificial reservoirs to conserve the water that falls from the heavens, have hitherto been the drawbacks that prevented the full development of this region.

(To be Continued.)

Mines and Mills of Shasta County.

NUMBER VII.

[From Our Traveling Correspondent.]

Extensive Reduction Works of the Calumet Co.

As stated in my last, the Calumet Co. owns on the same line of lode of the Walkers. This company has 3433 feet, embracing the Grand Prize, Wedge and Washington mines. The lode runs in a northerly direction, crops boldly, and is from 4 to 10 feet wide. The whole line of croppings is heavily sulphureted. In milling, it gives from one to two per cent, so there is no end to sulphurets that will average $100 per ton, I would judge. The rock carries free gold as well. A large amount of work has been done on the three several mines in way of shafts, tunnels, stopes, etc., and yet the depth reached is not 150 feet. Hoisting machinery is now on the ground for erection.

Ore dumps, having near by the terminus of a tram road, receive ore from the several mines. At the southern end of the claims a tunnel has been started on the lode, which is now in some 200 feet, and which it is proposed to continue for the entire length of the claims, which, continued, would come out into daylight on the opposite side of the mountain in about one mile. At the mouth of this tunnel is another branch of the railroad, which leads to the mill, a distance of about three miles.

The ore is transferred to mill by mule-power, but the company expect to put down in the near future a Trail and place thereon an electric motor. On the line of this road, which has a regular grade, there are a number of trestles over which the mule travels unconcerned, the highest being 52 feet. To the south of the mines above referred to, the company owns several other properties which are being worked, one of which—the Poorman—has hoisting works already on. This is a smaller mine, but richer, the lode being from two to four feet in width.

Following the road down, we soon take in a fine view, including the Sacramento river, surrounding hills, valleys and fine grounds and mills of the Calumet Co. The road terminates some 60 feet above the mill, where the ore is dumped into chutes.

These works being the largest and finest in Northern California, we set ourselves down for giving an extended review of them.

The mill-site is certainly the finest, most elaborately laid out one, not only in California, but of all the mining States we have traveled in. One does not comprehend, until he is on the spot, how systematic, practical, novel, neat, and complete every part is.

The mill-site consists of 20 acres patented ground, and is situated six miles above Redding in this same Old Diggings Mining District, on the east bank of the Sacramento river, and within a stone's throw of the California & Oregon railroad, which is on the opposite side. The ground rises gently from the river, having moderately high hills in the background. The place originally was an Indian rancherea, then the locale of the placer miner; now four mills and one furnace with fine grounds have taken their place. The regular crushing works consist of 2 Paul 12 stamp circular batteries, making 24 all told; these have a reducing capacity of 40 tons per 24 hours.

These mills have attached to them a full complement of silver plates and a new oscillating blanket concentrator. There is also 60 feet of the Robbins riffle. The plan of working is:

1st. Crushing the ore by a Blake breaker.

2d. Stamping to No. 8 screen. They amalgamate in the battery. The pulp flows over a large surface of silver plates, then on to the oscillating blankets, which are used mainly for taking up the gold, and will not amalgamate; also sulphurets. Then comes the Robbins riffle, where more or less sulphurets are also saved; the pulp, relieved of the sulphurets, passes on to the "Americanized" arastras (which have stone bottoms and drags). The tailings, as we will now call them, are worked on "arastra" fashion; silver plates are so arranged that no pulp passes off without passing over them. The arrangement is very complete and practical. There are four of these arastras, which we should state are also a Paul invention; each battery has the same complement of machinery.

Every millman will say that this is very thorough working, and yet they have a loss, which makes the stamps, with the use of water, compared with the results of their dry working, unsatisfactory. We were told there was so much difference, after the best work that could be given by battery working, as to make it likely they would stop the stamps altogether, excepting when they would work low-grade ore, simply for concentrating the sulphurets it might contain. This assertion made us look at the dry mills with greater interest. There are two of these mills some 500 feet apart. We neglected to say to start with, that all the works are run by water-power, the source of the water being about 8 miles from the mills. The water-right covers about 3000 inches, but for the most of the year there is not over 500 inches available, and this falls to about 200 inches in the last month of the hot season; still, having 250 feet head, they have a vast power at command and more than they now utilize. The water-wheel used is of the Knight pattern; they also use the Knight hydraulic gate, by which a boy can start or shut off all the machinery with the greatest ease. To bring this water from its source there is, with the ditch and flumes, some 2000 feet of 3 feet diameter iron pipe, for carrying the water from the top of one hill to the top of another. All the ditches, flumes and pipes are on the west side of the river, and terminate at an elevation some 250 feet above the point required for use. All water not actually required for use is turned down into the Sacramento, while the amount required is conveyed through another gate to the pipes that lead to the works.

At the terminus of the ditch commences a line of pipe down the hill, and this gives a pressure of about 200 feet perpendicular. The works being on the opposite side, it became necessary to build a bridge, and there is now built one of the strongest and neatest wire-suspension bridges we have seen anywhere. It is one span of 325 feet from tower to tower. On this bridge is laid the large 16 inch pipe which carries the water. The bridge has a capacity of holding 40 tons, although only about 18 is now on it. The bridge is a great local convenience, as it is allowed to be used for a free foot-bridge, there being a good walk on either side of the pipe. From the bridge, the pipes run some 500 feet on trestle-work to the mill. It was a big and expensive work getting the water to the mill, but once there, all miners can appreciate its value and saving. The entire cost of bringing this water to mill was about $70 000. Water is used in one set of mills, then passes on some 500 feet to what is called the lower mill, where it is used over again. This same water can be utilized several times by carrying it on down the river banks. As to the dry mills, we found these especially interesting from the fact that the process and mode of operating machinery was new and novel. The larger mill adjoins the battery-mill and is driven by the same power. As we throw our eyes up to view the machinery, we see prominently posted what in part explains the mode of working: "The Paul Dry Amalgamating Barrel Process," patented. All ores are amalgamated dry in cylinders, but to have it more comprehensive to the reader as it is new, we will give the operation from the rock-breaker down.

The breaker is a "Gates" which reduces the ore to about a No. 3 wire screen, reducing at the same time a large percentage much finer. This ore is reduced is elevated to a revolving screen, No 5 mesh, which sieved ore is conveyed to the dryer, while the part not fine enough is returned to the crusher. The ore is dried by steam pipes, instead of fire. As soon as the ore is freed of all dampness, it is transferred to the self-feeder of the pulverizing barrel, which automatically feeds for pulverizing to No. 60 mesh. From the pulverizer the ore is conveyed to another hopper, from which it is transfered to the amalgamating barrel, where it is charged with a large per cent of quicksilver, and such chemicals as are suitable to the ore worked; the charge is then revolved for a given length of time, and this depends on the ore worked, when it is ready for discharging.

When the operation is concluded, in every particle of the charge, mercury in a very fine state can be found; no teaspoonful of the heavy charge but contains it, showing it has permeated every particle. We must say that we are strongly impressed with this system of amalgamation, and especially where the gold is fine. The question in our mind was, as no doubt it is with the reader, how could all this fine 'quick' which must carry the gold be brought together and without serious loss. This point was soon solved to our satisfaction, by Mr. Paul, who favored us with his presence and explanations in examination of the works.

The amalgamated ore was now discharged into a second cylinder, which was charged with hot water, and further chemicals. This cylinder was now set in motion and revolved for a given length of time. When ready for discharging a small valve is opened, and without stopping the cylinder, and to our surprise, the quick began to flow out of an iron pipe in a good-sized stream, until some 100 pounds had been discharged into a receiver; this being the amount used in the charge. But this Mr. Paul said had no gold in it, which was another puzzler until explained. The explanation is, that when the valve is opened, the quick leaves the cylinder and passes into the amalgam safe, which is a regular safe with a lock and key, where the amalgam is deposited, and then the mercury flows off into the receiver to be used again. This safe is also Paul's invention. In using this safe no one sees, knows, or can handle any amalgam except the party who holds the key. It is a complete operating contrivance, and works to a charm. The ore which now requires washing off, passes over a silver plate and vibrating table having silver plates; this table is a check for taking up any small particles of quick that might not have gathered in the first operation. From this table the ore passes over an oscillating blanket concentrator, where the sulphurets and other metallic substances are taken up. At stated periods the blankets are washed into a receiver below, from which they pass off to a reservoir especially for sulphurets; the residue now passes off as valueless tailings, and we think they are. The oscillating blanket tables are 14 feet long, and oscillates as the material to be concentrated is washing over, so the surface of the blanket is all the time free of sand piles, so usual on stationary ones. They worked well.

Some 500 feet down-stream from mill just described is another of the same kind. This mill also runs by water-power, the waste water from the other mill being run underground to the mill below. At this place is also a large reverberatory furnace, one of the most complete we have seen in our travels. This furnace is for treating the sulphurets as gathered by both the wet and dry mills. When the sulphurets are completely desulphurized, and while they are in a heated state, they are fed and treated in the same manner as in dry mill described, excepting the sulphurets are reduced to flour in fineness.

Not wishing to pry too closely into the business of the company, we did not get at the per cent saved by this plan of working, but were informed that, all things considered, it was far more profitable than either chlorination or the plan of disposing of the sulphurets. So much for the mills.

We now look around and see in front the cold, clear Sacramento river, and to the right of the mill, and between it and the river, is a good-sized orchard and vineyard—in fact on both sides of the mill is an orchard. On the place are peach, pear, apple, apricot, nectarine, quince, cherry, olive, orange, English walnut, fig, plum, Italian chestnut, black walnut, almond, and other kinds of trees of best varieties and all kinds of berries. Not only has great attention been given to fruits, but there are some 300 feet of flower-beds that grace the grounds. There is quite a large variety of roses and all of the finest varieties. They raise all the vegetables required for their use, and melons in profusion. Order and cleanliness seems to be the first law about his place. All buildings are placed in line with the mills, and in front of all is an avenue of some 35 feet in width and about 400 feet long, and this is lined with shade and fruit trees and flower-beds, the mulberry being a very conspicuous tree. On the line several large oaks also grace the grounds. The gardens, orchards and vineyards are inclosed with picket fence, and all, including the buildings, are whitewashed. The contract between the green and white is fine to view. Having an abundant supply of water, after its use as power it performs another duty in irrigating the grounds.

This spot was wild when the company first settled upon it, but little over three years ago. It is one of the grandest marks of what changes capital, industry and taste will do in the way of making a waste blossom as the rose. In the way of living, the employes of the Calumet must fare well, as all share in the good things of the company's grounds. We neglected to state, which our remarks call up, that chickens, turkeys and pigeons seemed plenty. The company work from 30 to 50 hands, according to season and requirements, and as they board their hands, they have a market for all they produce. They work on the principle that money saved is money made. The Calumet Co. is an Ohio company, Ohio capital entirely. Dr. W. H. Garlick is the president, and Almarin B. Paul, one of the oldest miners on the coast, is general manager. Mr. Paul has been manager from the start, and to his taste and industry all is due. All things considered, we cannot otherwise than extend our appreciation for courtesies tendered.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Alameda.

CHROME.—Livermore *Herald*, July 26: The James Mendenhall chrome mine is turning out a large amount of ore, and will begin hauling in a few days.

Amador.

HARDENBURGH.—Amador *Ledger*, Aug. 2: The Hardenhurgh mine is drained to a depth of about 400 feet, leaving about 50 feet more to reach bottom. James Evans has resigned from the superintendency and has been succeeded by Mr. Howland.

Butte

MINING DEVELOPMENTS.—Oroville *Register*, July 28: This summer shows more active mining developments in Butte than for many years past. Some of the richest and best mines are tied up in lawsuits, but in new mines there is much push and activity. Mention has been made of the great work done on the Golden Gate. The sale of the Greek mine and the old Cape claim was consummated and the money paid on Saturday last to the various owners. The rich returns from the Forhestown mines are attracting capital and a number of new ledges give fine indications for the future. Lately full details were given of the new mill going up on the Perkins & Gallagher quartz mine. The Palo Alto M. Co., near Buckeye, have purchased the Douglas mine, owned by Messrs. Farnham, Rowell, Gabriel and others. The American Eagle mine and others in the same neighborhood are being developed. The Patterson gravel mine, near the famous Carr mine, is paying from $8 to $50 a day for four men. The Carr mine is known to be very rich. The Reese mine, owned by Messrs. Reese, Walker & Smith, is being opened by a tunnel. The Rainbow mine, near Yankee Hill, is paying very handsomely. Others might be instanced, but enough names have been given to show how active mining developments are this season. The amount of gold shipped from this town is not less than $25,000 a month, while the shipment by private parties, mostly Chinese, is very large. Mining in Butte is only fairly started and within five years it will attain such proportions as to attract attention in all quarters.

GOLDEN GATE.—Work on the Golden Gate mine is being pushed ahead with all possible dispatch. Men are working night and day to get in the head dam and finish the big flume. We drove out to the mine on Tuesday night at half-past seven and found a large number of men at work filling in the cribs with as heavy rock as could be handled. The big rocks will remain without moving until the timbers themselves rot down. The long flume is already in place, though the bottom boards will not be laid till the water is ready to be turned in so as to prevent shrinking up and allowing the water to escape. Only one crib more was needed to be put in place to begin raising the stream. The river has fallen very rapidly and is now within five feet of low water. Unless some unforeseen accidents happen the mine will be opened in good season and there will be every facility for working the whole bed of the river in a most thorough manner. The greatest energy has been displayed by Manager McLaughlin and every possible contingency has been provided for. The mine is one of the busiest spots in the State, and work never ceases during the whole 24 hours of the day and night.

WORKING CEMENT.—In this county there are vast deposits of cement that have long been thought rich enough to pay well to work. Hitherto all attempts to get the gold have proved failures. In an early day a mill was started at or near Bangor and run for some time. Owing to the great number and extreme hardness of the rocks which were contained in the cement, the mill was finally stopped. On top the cement paid well, but deeper down the pay grew less. It was thought the pay streak had been passed through, but the miners did not begin again nearer the surface on account of the difficulty they had in working the very hard rocks. Twenty or more years ago Captain Darrah and Thos. Callow took a large quantity of cement from the deep beds of it, near old Lynchburg, a mile south of Oroville, and attempted to work it by a steam process at a sawmill that was running at the upper end of town. After a two months' trial they gave up the effort as unprofitable. Attempts are now being made to successfully work the rich cement in the Cherokee mine. There are vast deposits of it there and it is said to contain from six to eight dollars a ton in gold. Should they be able to grind this up successfully and obtain the gold, it will induce the building of a mill at once. Several parties from S. F. have leased ground at Cherokee and are now putting up machinery to test this deposit. Should the tests be successful they will open a wide field for profitable gold production.

Calaveras.

AROUND ANGELS.—*Mountain Echo*, Aug. 2: The Utica mine is in full operation day and night and the scene at the mine is that of general activity. The 60-stamp mill is kept in almost constant motion, the full complement of stamps being employed crushing ore. The work of sinking the old Leeper shaft goes steadily on, while work in the various stopes in the north end is being prosecuted with a vim. There is abundance of ore in sight in these stopes. The mine is yielding good returns. The Angels mine is being operated day and night. Work is progressing in the Potter shaft constantly, and as nearly as we can ascertain, the mine throughout is looking excellent. The work of sinking the Stickle mine is kept up day and night and with satisfactory result. The contract let calls for the sinking of 200 feet, which, when completed, will make the shaft 600 feet in depth and on a level with the north and south shafts of the Utica mine. The Gold Cliff mine is again in running order and the work of extracting ore is being carried on briskly. The mill has been overhauled within the past two weeks and in many ways improved. Messrs. Hallock and Hickok are working their mine west of town and extracting a good grade of ore. They are crushing their rock in an arastra at present, and we are informed that the ore pays sufficiently to warrant putting up a 10-stamp mill, and this the owners intend doing in a few months. The work of extracting ore in the Lane and Tulloch mine goes on steadily. The mill, which, by the way, has been increased to ten stamps, has been started up and is now in excellent running order. The mine looks exceedingly well. The chlorine works east of town are kept in constant operation. The furnaces are kept employed roasting sulphurets from the Utica mine and other mines. The present capacity of the works are inadequate to roast the increasing supply of sulphurets, and in consequence, new works similar in size and construction are to be added, the bricks for the construction of which are now being made. The work of building the additional furnaces will soon be commenced.

THE UNION MINE.—*Prospect*, Aug. 2: The English company which formerly operated this mine, and which owns it, has squared all outstanding accounts, it is said, and is about to open up again with an increased force. Teams are already engaged for hauling timber, etc., and a force of 50 men will be required almost immediately. The superintendent is now on his way here to take charge and prosecute the work.

Fresno.

VALUABLE IRON ORE.—Fresno *Republican*, Aug. 1: P. B. Donahoo and wife, C. Nelson and wife, M. Denicke, C. Beck, J. Robinson, and Peter and John Hansen left yesterday to inspect a valuable iron ledge just discovered this side of the iron deposits of the Minarets. The ore assays 68 per cent iron, being one per cent higher than the richest ore from the Minarets. Samples have been sent East for assay, and if the proportion of phosporus in the ore is not too large, Eastern capital will step in, build a railroad from this city to the mines and develop them.

Inyo.

BORAX.—Cor. Inyo *Index*, July 28: The prestige of this section (Alvord) is soon to be restored in the matter of borax shipments. Mr. Shober will leave here with his ten-horse caravan on the 1st of August for the borax fields to load at the works of Conn & Trudo, and Alvord will probably continue to be the main point for shipment from Saline. The news from Sylvania this morning indicates the immediate resumption of operations at the Kinkead claim, the kicks, splits and prolonged song-and-dance having all terminated in putting things in that prominent camp on a basis of sure development. The unvarying statements of the miners and experts as to the richness of the claim will soon be tested by the completion of the furnace and production of bullion.

ORE SHIPMENTS.—Inyo *Independent*, July 25: Shipments of ore from mines at the south end of the county have fallen off considerably the past few weeks. During the hot weather, usual at this season, miners leave the camps and go to the fishing-grounds in the heart of the Sierra mountains or to other resorts for a few weeks' vacation and rest. With the return of cool weather, the usual output of ore will be resumed.

SODA.—All the men that can be got are being put to work at the soda works at Keeler, taking up the new crop of soda. The quantity in the ponds is reported above the average, and the work of gathering will continue several months.

CERRO GORDO.—A promising strike of ore is reported in the Union mine at Cerro Gordo. The ore body has not yet been developed enough to show how extensive it may be. The quality of the ore is of the usual average found in the Union mine.

SYLVANIA. — Inyo *Register*, July 31: Present appearances indicate that the camp's dark days are over. The men have been paid, and all the hands available have been put to work on the furnace. An extension of time has been granted the purchasers in which to make final payment.

Mono.

THE STANDARD CON. MILL. — Bodie *Miner*, July 28: While not yet a matter for general rejoicing, it is still a gratifying fact that the old Standard Con. 20-stamp mill, which has been lying idle so long, was again started up last Wednesday for a short run. Let us pray that it may be for a long run and a prosperous run to the mine and mill owners, for their prosperity means the general prosperity of us all.

Nevada.

ST. JOHN.—*Tidings*, July 29: The St. John's machinery has been started up and has been running smoothly. The buildings and plant have been put up in the most substantial manner. In fact a more workmanlike job it would be hard to find. The pump was to have been started to-day, and in a few days sinking will be commenced.

GREEN MOUNTAIN. — *Tidings*, July 24: The sheriff to-day sold the property of the Green Mountain Consolidated Mining Co., comprising the claim commonly known as the Sanders ledge, in this district, together with improvements, for $675, George G. Allan of Nevada City was the purchaser.

A RIVER CLAIM.—Grass Valley *Union*, July 30: Of late, a number of mining claims has been located on the Yuba river. Just now the river is about "clean" to the bedrock, and there are some very rich deposits along its channel. James Pollard of this place, together with George Treat, T. C. Bourne and others, have located about 2½ miles of the river between the South and North Forks, not far from Bridgeport, and they will ground-sluice the river-bed. The claim embraces about 120 acres, and it is thought to be very rich.

DELHI MINE.—*Tidings*, Aug. 1: Not much has been heard of the Delhi mine of late For several years it has paid handsomely, but the shoot is a small one and has been exhausted in the upper tunnels. A tunnel from near the level of the river is now within a distance of 80 feet of the point where it is expected the ledge will be cut, and is being driven ahead with all expedition. All the indications bear evidence that the ledge goes down and will be cut where expected. When this is accomplished we will again hear of the Delhi's richness.

RIVER MINING.—Next spring and summer will witness lively operations on the Yubas, in the line of river mining. That there are tens of thousands of dollars in the gold in the river washed down from the hydraulic mines during all their years of operations is well known, and now that the beds are scouring out the prospector is on the alert. Rich strikes, such as were made in river mining in the early days, will be heard of during the next year or two, and old miners will, in the days of their physical decay, reap the fortunes that have eluded them throughout the toiling years of their youth and prime.

SEVEN-THIRTY,—Steam was turned on the Seven-Thirty mine plant Thursday evening for the first time and everything worked lovely. Saturday the four-inch pump will commence work, and two weeks hence the boys expect to have some good-looking rock to show their friends. Supt. McSherry informs us that the shaft on the Emmett is now in water, but there is not more than can be easily handled by buckets. The ground is much easier and the ledge has widened out to nearly three feet. Some beautiful ore is coming from the shaft. The Manhattan machinery will be ready to start up some time next week.

Placer.

THE MOORE.—*Herald*, Aug. 2: The *Herald* from time to time has had occasion to refer to the phenomenal richness of the Moore mine, about a mile and a half west of Auburn at the south base of Duncan hill, and owned by Thorpe and the White Bros. Last Saturday Mr. Thorpe brought to Auburn the cleanup from a crushing of 18 tons of ore, 12 tons from the main shaft and six tons from a prospect shaft 300 feet east of the main works. It weighed 266 ounces and 8 pennyweights, and was worth $4300, showing a yield of about $240 per ton. The ore is equally rich in the shafts, 300 feet apart, and at any point between the ledge prospects as well as at the shafts. Thus far they have taken out no rock except in sinking, and they are not very deep, and yet they have realized already a small fortune.

Plumas.

CAPITAL NEEDED.—Cor. Plumas *National*, Aug. 2: The Challen gravel mine is being opened by a company of Minnesota capitalists, with every assurance of having a rich paying mine in the near future. The main channel has already been tapped by a long tunnel, and the prospects obtained fully warrant the company in prosecuting the work. Now, what this county needs, and this section in particular, is capital to open the mines. Here are numerous channels running through the different ridges that overtop the rivers, creeks, gulches, basins and bars that have yielded their millions, and the fountain-heads that fed them comparatively untouched. The resident miners are too poor to run bedrock tunnels, hence the need of capital. There are many good mines in the county that are in successful operation, but this fact is scarcely known outside the limits of the claims.

THE JOHNNY BULL,—Greenville *Bulletin*, Aug. 2: Messrs. Firmstone, Richards & Old are pushing work on the property. The tunnel is now into the hill about 150 feet. The face of the drift is in a nine-foot ledge, which is between well-defined walls and standing at an angle of about 45 degrees. The five-stamp mill is running on ore taken from the tunnel only. Stoping will begin soon. The ore is paying from $6 to $8 per ton. Only six men are required to mine and mill the ore. It is a property that can be operated very cheaply in every respect. The owners have paid for their mill and discharged much other indebtedness incident to developing the mine, and they are now in a position to make money.

THE SAVERCOOL.—From Alex. Cameron, superintendent of the Savercool mine, we learn that work on that property is progressing favorably. The six-foot tunnel is being run in the quartz vein, which prospects well. The large mill is to be repaired and furnished with water-power. In supplying water-power, two propositions are under consideration—one to cut a ditch from Ohio valley and the other to utilize the water in the North Fork below the mill. The company has invited the submission of plans and estimates. The corporation seems well satisfied with the developments made by Supt. Cameron, who now thinks the mill will be running in full blast within six months.

San Diego.

PINE VALLEY.—Cor. Julian *Sentinel*, July 25: Our camp is slowly but surely progressing in the work of development. We are fully satisfied with present developments for the simple reason that the mines invariably improve as depth is attained. Our mines are located on a belt of micaceous and talcose slate, the very nature of which is proof sufficient of the cheapness of extracting the ores. Our ores are, without exception, free milling, gold-bearing quartz, carrying a certain percentage of silver and sulphurets; the veins being well defined, showing good walls on both sides, indicative of true fissures, running northwest and southeast, with a slight dip to the east. The Oxide, usually known as the Wilcox mine, has been opened by a tunnel tapping the vein at 35 feet, showing three feet of good free-milling ore and milling $7 a ton. The Acme shaft is down 30 feet, showing three feet of $8 rock. There are four parallel veins on the location within 60 feet of each other. The Emmeline is opened at a depth of 25 feet, showing a seven-foot vein of $5 rock, which can easily be sorted to $12. A shaft is being sunk on another ledge on this location which is rich in free gold. The vein is from 6 to 18 inches wide, and will average $25 per ton. A pocket was encountered last week showing some very rich specimens of native gold. The above properties are owned by Beam & Kerby. The Columbia, one of a group of mines owned by T. L. Williams, is down 17 feet, a shaft being sunk on a junction of two distinct ledges, which combined measure 4½ feet in width of quartz that will average $11 per ton. There is also a tunnel started to tap the ledge, the face of which is within 15 feet of the ledge. Mr. T. D Los Clarke is engaged in tunneling for the Saddle mine, from which some excellent prospects have been obtained. Noble Bros. & Co. are milling some of the richest quartz in Southern California. It is actually covered with coarse native gold. The ledge averages 15 inches in width. They are also sinking a shaft to tap the Spring mine from which great expectations are entertained, as the quartz in the old shaft has milled somewhere in the hundreds. They also own the Bay View and the Alpine lodes. Goodbody & Co. are tunneling on the vein of the Mollie G. lode, the vein showing signs of improvement both in size and quality of rock. They also own the Gold Bank mine.

GOLD QUEEN.—Julian *Sentinel*, July 25: Supt. Wilkins informs us that the new shaft at the Gold Queen is now down about 50 feet. The hoist will be ready for operation in a month's time. The ten-stamp mill ordered of the Coronado Foundry will be completed in two months.

THE KENTUCK S. — Julian *Sentinel*, July 25: We visited this mine at Banner and met Major Werlitz and Mr. Pannenberg. Work on this property has only been in progress since the 15th day of June. There are three known veins or ledges running through this property, and known as Kentuck S. Nos. 1, 2 and 3. From the dip or angles of these veins a close calculation will bring them together before the 500-foot level is reached. The main working shaft is situated between Nos. 1 and 2 of the veins, is three compartment and is now down to a depth of 60 feet. Two crosscuts are being run, one northeast to cut vein No. 1 and the other southwest to cut Nos. 2 and 3. The work of timbering is the finest we have seen in the camp outside of the great Stonewall. The grading for the engines, boilers, hoist, carpenter and blacksmith shops, ore bins, etc., is about completed. Lower down the hill a tunnel has been started on vein No. 3. In cutting away the mountain and facing up for the tunnel proper required about 30 feet of a level on the ledge. Before ten feet of earth and stone had been cut away they opened out a surprise for all the old-timers. An immense ledge was uncovered showing up free gold. At the face of the tunnel the ledge measured is fully five feet in width. On the dump are 80 tons of a fine quality of low-grade ore that actual tests prove will mill about $18 per ton. No other company has ever come to the camp and accomplished so much in so short a time. This mine is now employing 24 men, two six-horse teams and one four-horse team. Their hoisting plant is on the way from the East and will be put in place as soon as it arrives, as it is badly needed now. As soon as the new road is completed, so lumber can be had, suitable buildings will be erected and teams will be put to work getting in wood and timbers for the winter. In a short time the force of men now employed will be doubled and we may look for lively times around the Kentuck S. before the winter snows come.

San Luis Obispo.

THE CHROME WORKS. — San Luis *Tribune*, July 25: From his recent visit to the soda deposits in the Carrisa Valley, Mr. H. D. Shaw, who is endeavoring to launch the proposed chrome works, returns much strengthened in his conviction that San Luis Obispo is decidedly the place to establish the factory. The deposits he examined are of very great extent and purity and admirably calculated for the uses he desires to make of them. Nothing in fact in the way of crude material is lacking in this immediate vicinity and it can be procured at very low figures, making the great financial success of the enterprise a certainty.

Sierra.

GOLD LAKE DISTRICT.—Grass Valley *Union*, Aug. 2: Theodore H. Wilhelm, Andrew Husom, George Mainhart, Chas. E. Uren, John M. Thomas, all of Grass Valley, and, Charles McCreany of Sacramento, all took a trip up to the Lone Star mine, in Sierra county. The mine is situated in the Gold Lake district, and has been worked enough to demonstrate that it is a valuable piece of property. The ledge in the mine is from three to seven feet in width and can be easily worked. Heretofore shafts were sunk along the line of the ledge, but we are informed that it is the intention of the company to run a tunnel in to tap the ledge. This tunnel will cut the ledge to a depth of about 100 feet. Chas. E. Uren made a survey of the property and the company have applied for a patent. Several large pieces of the ore from the Lone Star, brought down by the party mentioned above, show well in free gold, and are heavy with other mineral containing gold. Mr. Mainhart thinks the prospect at the Lone Star is an exceptionally good one.

NEVADA.

Washoe District.

ORE AND BULLION YIELD.—Virginia *Chronicle*, Aug. 2: This week's ore yield of Comstock mines aggregated 6088 tons, divided as follows: Con. Cal. & Va., 1680, assay value $17.60 per ton; Savage, 446 tons, assay value $25.40; Yellow Jacket, 490, assay value $21.50; Crown Point, 790, assay value $16 99; Justice, 203, assay value $26.63; Alta, 325, assay value $20; Overman, 556, assay value $17; Challar, 463, assay value $25.70; Belcher, 332, assay value $25.94; Ophir, 803, assay value $31. Following was the bullion yield of the ore product from each of the above mines, estimated on the probability that 80 per cent of the value of battery sample ore-pulp assays was returned: Con. Cal. & Va., $23,650; Savage, $10,000; Challar, $9500; Yellow Jacket, $8430; Crown Point, $10,750; Overman, $7560; Alta, $5200; Justice, $4320; Belcher, $8600; Ophir, $20,000. Total, $108,000.

SIERRA NEVADA.—On the 630 level at a point 16 feet from the face of the west crosscut, 600 feet from the shaft station, a north drift is advanced 133 feet continuing in clay and porphyry, showing low assay value.

UNION CON.—On the 1465 level from the north lateral drift, opposite west crosscut No. 4, east crosscut No. 1 is advanced 639 feet, continuing in porphyry carrying clay separations and fine lines of quartz.

MEXICAN.—On the 1465 level, east crosscut No. 1, opposite west crosscut No. 5, is advanced 56 feet, continuing in a porphyry formation carrying low-grade quartz.

OPHIR.—On the 1300 level the winze being sunk below the sill floor of this level, at a point 10 feet southwest of the raise, is down 108 feet, the last eight feet of which includes a north compartment or two sets of timbers. An excavation of the same extent has been made on the west side, making the whole opening the size of four sets of timbers, all of which is in ore. About 50 tons has been extracted therefrom, assaying from $25 to $30 per ton. The ore on the northeast side of the winze appears to be better quality than that on the northwest side. Hoisted during the week 278 tons of ore and shipped to the Morgan mill 803 tons, the average assay value of which was $31.26 per ton. Total ore shipped to the Morgan mill, 883 tons and 1630 pounds. All of this ore will be milled and the bullion returned in three or four days. No more shipments will be made at present.

CON. CAL. & VIRGINIA.—The 1300 and 1500 levels continue to yield the usual quantity of ore. On the 1200 level in the south drift at a point 425 feet south from the Con. Va. shaft, east crosscut No. 1 is advanced 30 feet in porphyry carrying quartz of low assay value. There has been extracted during the week, from all parts of the mine, 1660 tons and 1170 pounds of ore, which was shipped to the Eureka mill, battery sample assays showing an average value of $17.60 per ton (1680 tons milled). Shipped bullion valued at $50,780.88 to the Carson Mint.

SEG. BELCHER.—A winze below the 1300 level,

directly under raise No. 1 above that level, is down 34 feet, the bottom in low-grade quartz.

JUSTICE.—During the week crushed 203 tons of ore showing a value of $26.63 per ton by battery sample assays. The raise above the 460 level is up 57 feet; top in fair milling ore.

ALTA.—The ore output this week was 325 tons, showing an average assay value of $20 per ton by pulp assays.

OVERMAN.—Shipped 556 tons of ore during the week showing an average value of $17 per ton by battery sample assays, of which $9 62 was gold. Are stoping ore from the incline winze below the 1200 level. The 850 level south lateral drift is out 41 feet; the face in vein matter.

OCCIDENTAL CON.—Continue to extract ore of fair quality from the stopes on the 400 and 450 levels.

BEST & BELCHER.—On the 1200 level west crosscut No. 1 is extended 114 feet. Formation, clay and porphyry with some quartz.

GOULD & CURRY.—On the 400 level the northwest drift is extended 231 feet. Formation, soft porphyry.

SAVAGE.—Shipped 490 tons of ore, showing an average value of $25.40 by battery sample assays. Extracting ore from the 300 to the 1300 level. Bullion on hand valued at $28,518.80.

ANDES.—The 350 level west crosscut is stopped.

HALE & NORCROSS.—Shipped on July account 2325 tons of ore, which has yielded $36,700 in bullion.

WARD COMBINATION SHAFT.—The 1800 level east drift is advanced 460 feet and the west 470. Both continue in porphyry.

CHOLLAR.—Extracted 463 tons of ore battery sample assays showing a value of $25.70 per ton. The 850 level east crosscut No. 2 is in 128 feet; face in quartz and porphyry.

POTOSI.—The incline winze is down 284 feet below the 930 level; bottom in porphyry, with streaks of quartz giving fair assays.

ALPHA.—The 600 level east crosscut No. 2 is in 90 feet from the shaft, the face in clay and quartz. The 600 level southwest crosscut is in 112 feet, face in clay and porphyry.

EXCHEQUER.—The 600 level north lateral drift is in porphyry.

CON. NEW YORK.—The 800 level north drift from west crosscut No. 1 is out 137 feet; face in clay and porphyry.

IMPERIAL.—The 1000 level west crosscut No. 1 is in 210 feet, the face in quartz and porphyry.

YELLOW JACKET.—Shipped 490 tons of ore showing average assay value of $21.50 by battery sample assays. East crosscut No. 2, 100 feet south of No. 1, will reach the vein next week.

CROWN POINT.—Shipped during the week 761 tons of ore, showing an average value of $16 99 per ton by pulp assays. The pay ore in the 300 level west stope is yielding as usual, and that in the east stope is growing narrower.

CONFIDENCE & CHALLENGE. — Joint Imperial west crosscut No. 2, 450 level, is in 276 feet, face in barren quartz. The joint Imperial north lateral drift is out 450 feet, face in porphyry.

Ely District.

THE CHAINMAN MINE. — White Pine *News*, July 28: The property of the Ely Mill & Mining Co. (W. G. Lyons, James McOmie, A. J. Underhill and W. N. McGill) has recently shown great improvement in the grade of the ore. They are now down 250 feet in ore that goes $200 in gold to the ton. The ore is baser than near the surface and may require roasting or smelting to treat it successfully. The work of development is going on and the mine is responding nobly to the labor done upon it,

White Pine District.

ACTIVITY.—White Pine *News*, July 28: In an interview with E. Shepardson of Hamilton, a few days ago, we learned that the mining prospects of that district are very bright just now. The following mining items of interest we give from his interview: Sam Paul has made a very important discovery near the summit of White Pine mountain lately. The ore goes 100 ounces in silver and 66 per cent in lead. The vein is large and promises to develop into a big mine. J. R. Kendall and George Allen are taking out very rich ore from the Alceon mine, just above Hamilton, and shipping it to Salt Lake. George Paul's mine, on the other side of the divide on the road leading to Shermantown, is showing up fine. Two men are taking out more ore than a 12-horse team can haul to Eureka, and it is of good grade. A. Jacobson, Gus Simon, Rocco Kranez and P. Peterson are taking out good ore from their mine on the western base of Treasure Hill. Tom Cornell has a good mine at the base of White Pine mountain, leased to Dave Ross, Tom Waters, Ed. Daily and Wm. Roberts, near McAllen's mine. The boys are taking out good ore and making money. A. Muir and John Brown are working the Elko mine on the east side of Treasure Hill, and are shipping ore. But, undoubtedly, the best mine in the district is that of McAllen Bros., at the eastern base of White Pine mountain. They will take out $10,000 this season and have a property worth $100,000

COLORADO.

SNOW MASS COPPER.—Aspen *Times*, July 26: There is a prospect of the Snow Mass copper properties being extensively worked in the near future. The copper ore that has been found there in the past has all been float, but it is such a regular form that the belief is entertained that the lode from which it comes is not far distant. The plan now is to thoroughly prospect the ground above for the purpose of finding the ore in place. The ore is very rich in copper, selected specimens running as high as 65 per cent. It all carries silver, the assays returning as much as 40 ounces in some cases, and the average appearing to be something like 15 to 20 ounces. The work that has been done has all been done in the broken ground where the mineral is met with.

BONNYBEL DUMP.—The dump of the Bonnybel is proving to be very valuable. It is under lease to Dan Santry, Fitzpatrick and others, and they are shipping quite heavily from it. They ship the ore to Leadville and are able to clear about $5 per ton on it. The dump is believed to contain fully 5000 tons of stuff that will pay to ship, and the lessees will realize quite handsomely from it.

A TIN CUP MINE.—The Jimmy Mack and Mary Meagher mines at Tin Cup, owned by the Brunswick M. & M. Co., are developing into a paying property under the management of J. S. Halsey. The property had been idle for 18 months, but work was recently started up on it again. There was a four-inch streak showing when Mr. Halsey began operations, but the vein has now opened out to a width of seven feet, 18 inches of which is solid ore that runs up over 100 ounces.

ARIZONA.

A BOND.—Prescott *Journal-Miner*, Aug. 3: W. U. Masters and W. H. Storms have taken a working bond, with privilege of purchase, on the Ohio mine, owned by Wm. Jennings, nine miles from town, and have placed a number of men at work developing the property. The mine has yielded some splendid ore. Mr. Pedley is pushing work on the Lynx creek hydraulic works. About 30 men are now employed on the dam, which has been built 15 feet high above bedrock. The dam is being built of masonry, and will be perfectly solid. Work is also progressing on the ditch. The new shaft of the Senator is now down 430 feet. A station is being cut out on the 420-foot level. A very large body of high-grade sulphurets was recently struck in the north drift, similar in character to the ore previously encountered in the south drift. The Wire Gold mill continues to pound away on ore from the Wire Gold mine. The Tuscumbia mill will be started up soon again. J. D. Helm expects to put the old Tiger mill in operation soon. Walter J. Wright will be in charge of the Tuscumbia mill when it starts. The Senator shaft is now down 450 feet. Mechanics are at work putting up roasters in Copper Basin, and that camp promises to be lively once more.

IDAHO.

STRUCK IT RICH.—Idaho *Avalanche*, July 26; Ike Phillips came down from the Phillips & Sullivan mine on Sunday evening, bringing the news that he had struck it rich. In running the lower drift south they have at length reached the chute of ore out of which, nearer the surface, the lessees of the mine a year ago had taken $20,000 in $150 ore. This chute has widened out to over three feet and is not only apparently much richer in silver than where worked above, but carries a much larger percentage of gold. Several parties have been up to see the new find during the week, and all pronounce it the richest they have ever seen on Florida mountain. Estimates place the value of the ore all the way from $300 to $1000 per ton. A drift has now been run on the chute a distance of 30 feet without any signs of its diminishing in value. As the drift is 123 feet below where work was stopped on it in the upper level, enough of this rich ore is now in sight to safely pronounce it a fortune for the lucky owners.

THE ONTARIO AND SUNOAY MINES.—Ketchum *Keystone*, July 28: We have been shown a dispatch from Major W. A. Rooks, general superintendent of the Ontario group and of the Warm Springs Mining Co., addressed to Mr. Milt Mourning instructing him to put men at work immediately on the mines of the company. This will give new life to this section of the country. The mines belonging to this company are the Ontario, Hub, Huh No. 2, Niagara, Hathaway, Old Abe and Sunday. Operations are likely to commence first on the Ontario and the Sunday. There is a great deal of tunneling.

THE PHILADELPHIA & IDAHO CO. — Wood River *Times*, July 31: It was rumored in town, yesterday, that operations would soon be resumed at the Ketchum smelting works, This rumor, the *Times* is prepared to state, was founded on fact. A letter of instruction ordered Mr. Hardess to increase the forces at work on the North Star and American Eagle group on East Fork and the Silver Star group in Smoky. Mr. Hardess was also instructed to appoint heads of departments or divisions of the calcining and smelting works. The "blowing in" of the company's furnaces will mean a great deal to Wood River. It will mean the employment of between 300 and 400 additional miners, teamsters, haulers, furnace-men, etc., and a revivifying of all our small industries.

ANOTHER CAMAS BRICK.—A $1200 gold brick was brought in yesterday from the Camas No. 2 mine and mill.

NEW MEXICO.

HILLSBORO.—Rio Grande *Republican*, July 26: The Garfield, Golden Era, etc., are developing and producing ore. The 85 is proving to be a good mine (C. K. Co.) and will soon add its share to the output of the camp. There are many excellent prospects in the camp that can be made producing mines, only needing a small outlay of capital. The Opportunity, Snake and Bobtail are all working and keep pounding away day and night on their ore, with their 20-stamp mill at Hillsboro. J. H. C. has commenced development in earnest on his Black Peak mines and expects within three months to be sending out gold bullion bars from the camp. Mamie Richmond, a steady producer of high-grade ore, recently sold for $6000 to Chicago parties, will now be more extensively developed. The Bonanza and Hope mines are working all the men that they can, conveniently. They are working their ore at their own mill, two miles from Hillsboro, (a five-foot Huntington mill and concentrator,) capacity, 20 tons in 24 hours.

KINGSTON.—Word has reached here from Kingston that the vein which was the source of the rich float found on the Solitaire mining claim has at last been found. Nine years ago a prospector discovered a lot of ore on the surface of this claim which was nearly solid silver, and $80,000 was picked up in one week, but all efforts to discover the vein proved futile until now a miner named Edward Coffey has opened a true fissure vein of sulphide of silver near this property which shows the richest ore ever produced in the camp, and is thought to be the "feeder" which furnished the solitaire ore. Fabulous stories are told of the value of the ore in sight.

MONTANA.

THE MINES OF ORO FINO.—Helena *Journal*, July 26: A Helena gentleman just returned from Oro Fino district, Deer Lodge county, informs the *Journal* that the mines of Champion give every indication of developing into permanent and rich producers. The latest strike, he says, was made on the Silver Crown's 100. The crosscut has reached the footwall, exposing 25 feet of vein matter, eight feet of which is solid quartz thickly interspersed with rich ore. The Champion's recently reported strike on the 500 is confirmed, five feet of good ore having been opened up. The Keystone Co. left good ore in the Washington at a depth of 135 feet, in order to go deeper. A crosscut will be run at the 200, which will undoubtedly open into good ore. The American-Ruby is going for the 350 with all possible speed. Every one prominently concerned in Champion properties is now thoroughly convinced that the Ore Finn is a deep country; that only depth is required to prove up one of the richest and most permanent districts in the State.

THE TOSTON SMELTER.—It is stated that the Toston smelter, at Townsend, which has been shut down by its recent purchasers, is soon to start again under a different management.

WILL INCORPORATE.—A movement is on foot among a syndicate of Helena mining men to incorporate a company to develop a group of valuable silver-copper properties in the vicinity of Radersburg, Jefferson county. The claims are known as the Silver Reef group, and consist of three locations, the Silver Reef, Henry and Green Copper.

THE HIAWATHA.—The permanent working shaft on the Hiawatha has reached a depth of 60 feet and will be pushed as rapidly as possible until the 225 is reached. At that point the workings will be near the lead, which can be tapped by a short crosscut. Most gratifying returns were received from a carload of first-class ore shipped last week, and the management feels greatly encouraged by the present outlook.

UTAH.

MOUNT BALDY MINES.—Salt Lake *Tribune*, July 26: Chas. Crane has been working some claims on Baldy mountain, in Gold Mountain district, about 30 miles from Beaver City. He owns the C. C. & D. mine, in which they have run a tunnel 40 feet on the vein. This vein is six feet wide, with a pay streak about two feet wide. Sixteen samples were taken across the vein and assayed separately, showing values from $26 up to $2760 per ton. Yesterday Mr. Crane received a letter from home saying that his men had struck some ore which is richer than any yet seen in the mine. The letter also gave information that the Sevier mine has been sold for $200,000. The Sevier is an extension of the C. C. & D.

THE ANCHOR BORE.—At the Anchor mine, Park City, a hole is being drilled down from the bottom of the shaft to the tunnel for the purpose of draining the mine. The distance between is about 600 feet; of this, nearly 400 feet has been cut.

SAMPLES.—Salt Lake *Journal*, July 26: Inquiry at our assay offices develops the fact that more samples of ore for assay and analysis are being received now than ever before. They are sent from every portion of the Territory, and represent new finds as well as abandoned tunnels and shafts.

EUREKA.—J. A. Van Pelt and G. E. Norton of Van Pelt, Norton & Harris of this city returned Thursday from Eureka, bringing with them samples from the Anor mine which assayed 75.8 ounces silver, 1.2 ounces gold and 4.6 per cent lead. The Anor adjoins the Mormon Chief on the north and the Sunbeam on the west. These gentlemen have control of this property, and are greatly elated over the prospects of the mine. Van Buskirk & Stebbins have recently closed a deal whereby they have obtained control of six claims in Eureka that are on a continuation of the vein tapped by the Bullion-Beck, Eureka Hill and Centennial-Eureka. Work will be commenced immediately on these claims, and the owners believe that they will develop into mines equal to any dividend-payer in that camp. Mr. Stebbins will go to Eureka next week. Capitalists and mine-operators are pouring into the Tintic district at an astonishing rate, and a great many new locations are being made there.

WASHINGTON.

AN EXCITEMENT.—Cor. Washington *Farmer*, July 28: The excitement up at the fork of the Cascade river—18 miles from this point, where that river empties into the Skagit and along the north fork of that river for 20 miles, including the Boston and Buffalo mines, on the summit of the mountain—where the Rouse Bros. have struck it so rich, is growing hourly. New finds of very rich silver ore assay from 60 to 65 ounces of silver to the ton, and lead from 60 to 65 per cent. The gold finds up to this date do not show over ten ounces of gold to the ton. Prospectors are pushing in every day from Ellensburg and Spokane, via Chelan lake, besides the parties who are keeping the road from Hamilton, Sedro, Anacortes and other points, in commotion en route to the mining fields. The people on the other side of the mountains along the Columbia river and about Spokane are much more excited over the silver finds about the summit than our people are on this side.

THE KOOTENAI MINES.—Spokane Falls *Chronicle*, July 26: Hon. J. B. Sargent returned this morning from an extended trip to the Kootenai mines. "We found the mines in splendid condition," said Mr. Sargent. "They are working them to advantage, too. The Silver King, Bonanza and Poorman mines are all turning out good ore and large quantities of it. All of the old mines are doing well and there are a number of prospects that promise good returns. In the Silver King they have struck a rich and solid vein of ore 12 feet across. In the Nelson district there is a new mine called the Tough Nut that promises wonderful things. They have struck a fissure of ore that promises to last as long as they care to work it. It is a very rich ore, too. New prospects are being opened right along and they are all doing well. Their greatest drawback at present is transportation, but that difficulty will probably be remedied in a very short time. The Northern Pacific and the Great Northern are both building into the district as fast as possible. As soon as the roads get in there the capitalists are expected to build a first-class smelter—nothing less than a 300-stamp mill and one that can work all kinds of ore. They figure that they can save the miners $6 per ton, the cost of shipping it to Spokane Falls. Lord Boyle and Dr. Campbell were looking over the mines while we were there and purchased two good mines, or rather one mine and a prospect. They paid a good price in cash for both, and as a consequence the mines throughout the district took quite a boom."

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING JULY 29, 1890.

433,116.—GRADING SCRAPER — L. E. Ashley, Stockton, Cal.

433,193.—WHEEL—Daniel Best, San Leandro, Cal.

433,072.—VALVE AND FAUCET—A. H. Dauchy, San Diego, Cal.

433,198.—VALVE AND FAUCET—A. H. Dauchy, San Diego, Cal.

433 165.—WATER-CURRENT MOTOR—Geo. R. Diggs, S. F.

433 201.—DIE FOR CUTTING METAL SCREWS—Geo. Gibbs, S. F.

433.172.—BICYCLE—John Jett, S. F.

433,173.—VELOCIPEDE—John Jett, Glen Blair, Cal.

433,130. — PRESSER FOOT FOR SEWING MACHINES—Crapo Leak, S. F.

433,131.—AGING WINE—Geo. H. Malter, S. F.

433,133.—WASHING MACHINE—E. McDonald, Willow, Cal.

433,305.—CAR COUPLING—W. Portlock, San Diego, Cal.

433,216.—ELECTRIC TRAIN SIGNAL — A. W. Reppy, Oakland, Cal.

433,098.—COMBINATION TOOL—T. P. Schwartz, Stockton, Cal.

433,104.—FEED-WATER HEATER—A. R. Smith, S. F.

433,110.—GAME—Dormer Walsh, S. F.

The following brief list by telegraph, for Aug. 5, will appear more complete on receipt of mail advices:

California—Alexander Johnson, Oakland, assignor to Marshall Improved Furniture Co., San Francisco, sash balance; Almon Ames, assignor to R. J. Davis, San Francisco, pile covering; Charles L. Burbeck, Fort Bragg, oil cup; Alvin T. Church, East Oakland, sash holder; Gertie D. Cluff, Lodi, garment supporter; Gilbert A. Cunningham, San Francisco, safety guard for railways; Samuel H. and C. L. Miller, Stockton, bay press; George W. Parker, San Francisco, street pavement; Assaria Rewrick, San Francisco, traveling block; Charles Silberstein and J. Amos, Los Angeles, smoothing iron; Clara Turney, Sausalito, horse-controlling device; William A. Zumwalt, Farmington, gang plow and harrow.

Oregon—Frank Batter, assignor of one-half to L. Clemensen, Marshfield, device for drawing beer; Richmond P. Smith, assignor of one-half to T. G. Owen, Marshfield, tool for manipulating insertible saw teeth.

Washington — Emma C. Hudson, Seattle, slate sponge.

Arizona—Thomas J. Thorp, Chicago, Ill., assignor of three-fourths to D. J. Brannen, Flagstaff, and G. M. Lockwood, Washington, D. C., wheel.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

AUTOMATIC ELECTRIC TRAIN SIGNAL.—Albert W. Reppy, Oakland, assignor of one-half to T. C. Masteller. No. 433,216. Dated July 29, 1890. This invention relates to that class of train-signaling apparatus in which a normally closed electric main current is employed in connection with one or more local circuits in the several cars and engines of the train, said local circuits, including an alarm, being normally inoperative or open but adapted to be closed and brought into action by the breaking or opening from any cause of the main circuit. The object of this invention is to provide a simple and effective apparatus of this class adapted to be called into action in any possible contingency, particularly upon the breakage of any portion of the train, the derailment of any of its wheels, or the will of any passenger, train-man or engineer.

SPRING PRESSER-FOOT FOR SEWING MACHINES. Crapo Leak, S. F., assignor of three-fourths to Mondula Leak and D. V. B. Henarie. No. 433,130. Dated July 29, 1890. This invention relates to certain improvements in presser-feet for sewing machines. The advantage of the device is very great, especially in sewing kid, leather, cloth, or goods of any description where seams lap or varying thicknesses of material occur in the line of stitching.

WHEEL.—Daniel Best, San Leandro. No. 433,193. Dated July 29, 1890. This invention relates generally to the class of vehicle wheels, and especially to those wheels which are to be used with very heavy vehicles, such as traction engines or road locomotives and other heavy implements. The object of the invention is to provide a construction which will permit the ready attachment of the spokes to the hubs and their removal therefrom when necessary.

GAME.—Dormer Walsh, S. F., assignor to F. H. Manker. No. 433,110. Dated July 29, 1890. This game or toy consists of an inclosed table having a smaller movable table fixed in it with the upper surface flush with that of the main table, a means for giving an impulse to the movable table and a series of marked or numbered pieces which are assembled upon the moving table and afterward projected therefrom, and an opening in the main table designed to receive some one of the marked disks which are projected from the movable table and to expose the number or mark thereon. Various games may be played with this device, the object being in each case to scatter the movable disks about the surface of the main table and to place one of them within the observation opening.

PROCESS OF AGING WINE.—Geo. H. Malter, S. F. No. 433,131. Dated July 29, 1890. This is a peculiar method of aging wine, by which the valuable aromatic and delicate flavors from wine vapors are introduced into the wine being aged.

MECHANICAL PROGRESS.

COMPOUND LOCOMOTIVES IN GERMANY.—Mr. Stsmhke of Berlin read a pspsr in Janusry last in which he gavs the rssults obtalnsd with ompound engines hy the varlous State railway boards of Germany. On Decembsr 1, 1889, thsrs were running 118 compound locomotives, and 87 wers on order. Of ths 205, 16 were express, 35 passengsr, 139 freight, and 15 tank engines. The Bromberg State railway bosrd, employing 74 of thess locomotives, reports that the coal consumption avsrages 12 per cent less thsn ths ordinary engins. The cost of ths compound is ahont $350 mors thsn of the standard engine, hnt ths cost of rspairs is no hsavier. This hoard strongly rscommends the adoption of compound frsight engines. Ths Hanover hoard, wlth 89 compound locomotives, rsports that failures in starting are not more numerous with compound than with ordinary locomotives. Ths steam snpply is always smple, and ths tractive power is grsstsr than thst of the standard. The prsmium for economy of coal consnmsd earned hy ths drivers of the compound is always higher than that sarned hy the drivers of ordinary locomotives, althongh a deduction of 5 per cent is made against the compound. The amount of spsrks thrown out of ths chimney is less than with ths standard locomotive. The Hanover-Cassel traffic office recommends that in future only compound engins should hs ordered. The Frankfort-on-Msin board reports a fuel-saving of 17 per cent in ths Nordhausen district and 18 per cent in ths Frankfort. The oompound runs steadily at the greatest speed allowed. The Magdehnrg hoard rsports that enginss engaged in a variety of work show only three to six per cent economy of fuel; the compound freight engines drawing heavy loads over long distances, from 15 to 20 psr cent economy.

BAND SAW FOR METALS.—English mechanics are said to depend much upon a tool whioh is bnt littls ussd ln America, namely, a band saw for metals. Its construction, as described, is similar to that of a heavy hand saw, with a third carrying whssl for the saw, the object of this being to remove ths up-moving side of ths hlads from the vicinity of the tahls, and thus leave a dssp throat through which a largs piece of work can bs passed or a wide plate turned. Ths third whssl is placed at the hack of the machins, ahont midway in the vertical hight of ths saw blads. The tempsr of the saw is slightly harder than that of thoss nsed for wood, and the tssth ars sharpened straight aoross the hlade hy a cutter with its tssth at the right hight to suit the teeth of the saw blads. This tool is ussd for cutting off the spines from stesl castings, ths snds of holts, to saw up steel, iron and copper plates to any form, and to rough out the jaws of sccentric rods and other forgings whioh would require ths nse of slotting machinse, and it cuts as well on s circle as npon a straight lins. The blads is lubricatsd with soap and watsr, and in a cut six inchss long throngh a steel connecting-rod jaw it works frsely and sstisfactorily. Not infrequently oirculsr saws of large dimensions are used for the same purpose, and, heing mounted on hsavy frames and fsd carefully up to thsir work, cnt off largs pieces of stsel, leaving nearly a smooth surfaos on the face of the cnt.

SAVING OF DEAD WEIGHT BY USE OF STEEL.—While looking over the exhihits of stsel plates for car construction at the O.d Point Comfort Convention, we were struck with the saving in dead weight already accomplished by the nse of steel center plates and stake pockets. At our request Schoen Mannfacturing Co. prepared for ns the following statement showing the approximate ssving in dead welght and cost hy ths use of pressed centsr plates and stake pockets on 4000 oars, built hy the Philadslphia & Reading railroad:

Saving in dead weight per car, by using pressed steel center plates and stake pockets, pounds	548
Average mileage per annum per car, miles	8,000

Five hundred and forty-elght pounds dead weight moved 8000 miles, eqnals 2192 tons moved one mile at $ 0426 per ton mile; this equals $9327 per car per annnm. Assuming that to he the cost for moving paying freight, one-half of this would he the cost of a non-paying load, as tho weight of the car ahout equals the average load hauled; this would he $4663 psr car per annum as the cost of moving the extra welght of oast iron center plates and stake pockets. On 4000 cars it would amount to the total of $18,652 per annnm. Taking 12 yeare as the average life of these cars, this would make the total sum of $223,824 savsd by the substituting steel for cast iron.—*National Car and Locomotive Builder.*

DISCOVERY OF NOVEL PROPERTIES IN CAST IRON.—Some specimens of oast iron which exhihit nnusnal properties, produced at one of the great stove manufactories in Alhany, New York, have excited much interest; the pieces of metal being about one inch in width, one-elghth inch in thickness, and some 15 or 18 inches in ength. Of these strips, some were twisted so as to form spirals, and others were wrapped upon coils. That oast Iron can be made very tongh, and even a certain amount of elastioity he imparted to it, is of course well known, hnt it ia nnusual, if not nnprecedented, for any metal employsd in stove foundries to hear such tests as those thns indicatsd. The twlsting and hending in this case were done hot, there being nothing ln ths specimens hnt a jndicions admixture of good irons and the absence of old scrap —ths fact heing also stated that the irons in qnestion represent the daily meltings of the foundry from which they came, all the stoves produced there having their plates of the same metal which exhibits this pecullar toughness. It is not asserted that, because the metsl will hear a torsional strain of ths kind described, lt is, thsrefors, unbreskable, thsrs bsing, of course, a limit to its remarkahls elasticity.

AMERICAN STOVES.—Ths *Engineering and Mining Journal* has this hint to Amsrican stove and furnace maksrs: For soms ysars past Amsrican stoves and furnaoss have enjoyed a wids popnlsrity on the continent of Europs. Their gracsful constrnotion, effectiveness as fnsl sconomizers, and low cost, havs specially captured the thrifty German people. Amsrican-made stoves, certainly superior to the English and Irish-made stoves, have undersold them in ths German markets, msinly hecanse of the superior facilties and contrivances adoptsd in mannfaotnre in this country. But the German objects to importing what he can make himself. Stove factories ars, therefors, springing np all over, and mors sspecially in the vicinity of Mannheim, whers so-called "Amsrican stoves" are hsing turned ont rapidly. The rssult of this has alrsady appreciably affected the exportation of Amsrican stoves to Germsny; and it may hs dspended upon that, as soon as the Germans perfect their mechanism and methods, and with cheap labor, thsy will hecoms formidahle competitors in our outside markets. In all ths repnhlios of South Amsrica, more especially, the Germans are now pnshing their producte, and in soms osses thsy ars even crowding ths English. As our Teuton competitors waste little time in commercial matters, it hehoovss American stove mannfacturers to watch their South Amsricsn markets. Eternal vigilanos and goaheaditivenesa are ths prios of commsrcial snpremacy.

MECHANICS AS INVENTORS.—Said Sir John Lubhock rscently in a lectnre to English workmen: "It is remarkahle how many of the improvsments to which wsowe ths marvelons development of our manufacturing industry have heen dne to workingmsn. Watt was a mschanical engineer; Henry Cort, whose improvements in mannfactnres were said to have added more to the wealth of Englsnd than the whole valne of the national deht, was the son of a hriok-maker; Hnntsman, the inventor of oast stsel, was a poor watchmaker; Crompton was a weaver; Wedgewood was a potter; Brindley, Telford, Mashat and Neilson wsre workingmen; Georgs Stephenson hgan life as a cowhoy at twopence a day, and could not read till he was eightesn; Dalton waa ths son of a poor weaver; Faraday of a blacksmith; Nswoomen of a hlacksmith; Arkwright hegan life as a barber; Sir H. Davy was an apothecary's apprentice; and Boulton, the 'father of Birmingham,' was a hntton maker. To thsse men, and others liks them, the world owes a deep debt of gratitnds. Ws onght to hs as proud of tbem as of any of our generals or statesmen."

A SPRING PROPELLED VEHICLE.—In ths rsoe for new and improved msans for propulsion, such as stsam, gas, foot and crank powsr, no ons ssems to have thought of ths conservatives energy of a coiled spring until a Sonth Carolina lnventor devsloped the idea, and appeared, throngh his attorney, at Washington, for a patent for the same. The fundamental idsa seems to he the attainment of a road vehiole to take the plsce of the velocipede and for other pnrposes. The idea may he applied to one or more wheels. The devioe is so arranged that when the traveler is descending a hill the gravity force is utilized in winding up the spring, so that snch energy may be expsnded in conveying the occnpant over the adjoining plain and in mounting the next inoline. A ratchst levsr is also attachsd, to add to the spring tension as it is expended in keeping up the onward movemsnt. A singls spring or series of springs may he nsed.

GOVERNMENT TESTS OF ALUMINUM BRONZE.—At the Arsenal in Watertown, Mass., recently a serles of tests were made hy Government officials to determine ths tensile and transverss strength, dnotility, elasticity, and compressional strength of aluminnm hronze. Bronze will enter very largely into the construction of the new Government gunhoats, and these tests are of great importanoe, inasmnch as alumlnum hronzs can be prodnced at less cost than manganese bronze, which is nsed at present. These tests were of the tensile and transverse strength only, and they were far more sstisfactory than had besn expected. The tensile strength was shown to he over 90,000 ponnds to the sqnare inch, whioh was largely in excess of anything ever before shown. The transverse strength developed was 6600 pounds on a one inch sqnare bar. This has not heen equaled hy any other metal, except the finest quality of orncible steel.

AMERICAN SCISSORS IN SHEFFIELD.—A trade whioh nt one time was regarded as one of the dying industries is again reviving rapidly—that in soissors. German competition, says the London *Engineer*, has heen excessively keen in scissors for domeatio use, particularly those in the cheaper qualitiss. The Americans heat hoth English and German of the tallors' soissors, which are perhaps the most important hranoh. Amerioan-made tailore' scissors are prsferred even in Sheffield.

SCIENTIFIC PROGRESS.

Tanning by Electricity.

We hsve severs l times alluded, in these colnmns, to the experiments in tanning by electricity which have lately hesn carried on hy an Englishman. Ths inventor has qnite rscently made some demonstrations on a commercial scale which hsvs elicited much interest.

It appears from the rsport of these experiments, as presented to the puhlio, that hy this invention slectricity is used simply to shorten the time reqnired hy ths usual process, and that lt possesass no other advantage. Why or how it rednoes the time, neither the inventor nor any ons slse has hesn ahle to show. Rscent experiments made in France have shown that when plant seeds ars snhjected to ths action of an electrio current, presisely in the same manner as the skins are snhjected to it, a similar rssnlt sppsars—that is, the sseds come forward much more rspidly and produce fruit decidedly superior to that obtained without ths nse of electricity. This is ons of the most rscently discovered mysteries of this most mysterious agent.

The chsmistry of tanning has long hesn perfectly nnderstood, and ths ssme chemical agenciss ars required whsn electricity is employed as when the process is condncted in the usual manner.

If we plaos soms gelatine in a test tuhs and sdd a little tannio acid, the gslatine will gradnslly becoms coagulated. Ths hides of animals are full of gelatine, and when thsss hides ars divested of hair and placed in a solution of the tannio aold obtained from nntgalls, oak bark, or from any othsr source, the gslatine in the hids is coagnlated, thns rendering it hard and dnrahle—the hids is converted into leather.

This nsw process, if rsports concerning it are true, seems to warrant the conclusion that it will work a great revolution in the important indnstry of tanning.

Ths leading fact to hs notioed in the metter is that it does not supersede ths present uss of tannic acid—it only shortens ths time required for its action. By the ordinary method, ahont two months are required to thoronghly coagnlate the gslatine, or oonvert the hids into leather; while, acoording to reports, the same rssnlt may he obtained by the additional aid of electricity in four daya. This shortening of time grsatly rednces the capital necessary to he employed, or rather turns over ths capital in about ons-tenth of ths time.

To do this, however, power is rsquired. In the present process the hides ars allowed to rest quietly in ths vats soms two months; while in the nse of slectricity the hides are placed in a revolving drum. Ths ons used in the experiment at Bermondsey was made of wood, 12 feet in diamster, 8 feet long, and rotated at 8 rsvolutions a minute. Turpentine and tannic acid were used to saturate ths hides, and a strong current of slectricity was oansed to flow through the liquid in the drnm hy msans of a metal hand which ran aronnd the interior of ons end to a corresponding hand on ths other end. We are not told how mnch power is required to rotate ths drum, or what would hs ths cost of keeping up the constant strong onrrent of slectricity.

Ths leather turned ont hy this expariment was prononnosd to he of excellent quality, and lt may reasonably he supposed that the extra cost for power and electrioity would he more than connterhalanced hy the sconomy of space and time secnred.

In Aid of Science.

Prof. Davidson of the Coast and Geodetic Survey is now at the summit of Monnt Conness with his equatorial telsscope and other instrnments necessary for taking observations for the great triangulation survey of the Unlted States that is heing continued from summer to summer. The triangulation of the Atlantio and Gulf Coast is nearly completed, hut the Pacific Coast will still take several years. The ohservations are taken only from the tops of high peaks, and when finished and compared with the position of the stars will furnish an absolntely accurate survey of the coast countries.

The work of triangulation, says the *Call* of thie city, is interesting and curious. Prof. Davidson and his assistants are stationed on the top of Mt. Conness with their instrnments. Off to the west, on the top of Mt. Diahlo, are stationed two men with an instrument called a heliograph, which is an ingenious arrangement of a piece of looking-glass which flashes the sun's rays through two round hrass rings.

This instrnment is sighted for the top of Mt. Conness, hnt as the big mountain cannot hs seen from Mt. Diablo the sighting has to be done by a delicate instrument, which determines its place aconrately. Every day, from sunrise until 10 o'clock in the mornlng, and from noon to l o'clock, and again from 3 o'clock ln the afternoon until sunset, these two men take turns at handling this mirror hy a clever arrangement of screws, whioh hold the glass at snoh an angle as to flash the sun'a rays through the two hrass rings and straight into Prof. Davidson's Instrnments on the top of Mt. Conness, 100 miles away.

A similar contrivance ls placed on Mt. Macho, to the south of Diahlo, and this is also tended hy two men. To the aouthwest of Mt. Conness is Round Top, whioh also has its little flashing machine; so, too, has Mt. Grant, away over in Nevada and northeast of the central point, and so also has Lone Mountain, situated in the heart of the Nevada desert and due east of Connsss. In the centar of all thsse converging rays of light is staticned Prof. Davidson, making his obsarvations and calculatione, and oorrecting the rsnlts at night hy ths positions of the stars.

HOW WE LOOK AT THINGS.—Prof. G. T. Patrick in *Science Monthly* says: "You and I see svsrything, to some extent, differently. You see things from the standpoint of your prsviously acquired groups of idsss; I from mine. Strictly, no two persons can ass the sams thing in the sams way, for it can never happen that two persons have preoisely the sams gronps of ideas rslating to any snhject. These depend on our past exparience, on our edncation, on ths heliefs of our times, on our various sects or parties, on our pet thsories, our intersats, and our desires. Here is a simple illnstration: Suppose an artist and an engineer, standing side by side overlooking a tract of country. What they perceive is the ssme; what they apperceive is wholly different. To the engineer the country presents itself as a possihle line for a railroad, with hare advantageous gradss, and thsre economic hridges. Before the artist is spread ont a landscape, with light and shade and harmony of oolors. Suppose, again, a plot of level gronnd in ths suhurhs of a city. A college student, riding hy, apperceives it as a possihle hall ground; a young girl, as a tennis court; a speculator, as an addition to town lots; an undertaker, perhaps, as a possihle site for a cemetery."

A CURIOUS PHENOMENON.—When the snn sets in the sea, a cnrious appsarance, as of a hlnish-green flame, is sometimes observed. This has heen thonght to be dne to the light passing through the crests of waves. But Prof. Sohncke oonsiders this view disproved hy such an observation as that recently made hy Prof. Langs, at a watering-plaoe on ths Baltic. Shortly hefors sunset the disk was dividsd in two hy a thin strip of cloud, and just as the upper part disappeared under the cloud, the hlne flame was obsarved. Thus the cause appears to be in the air, not in the sea. It is a oass of atmospheric refraction. And as a planst, seen near the horizon with a good telescope, appears drawn out into a spectrum, with the more refracted hlue-violet end higher than the red, so the last visihle part of the snn furnishes the hlue-violet end of a spectrum.

A SUNKEN MOUNTAIN.—It is rsported apparently upon good authority that a mountain peak, nearly 1000 fset high, in the Coast Range of Oregon has recently disappeared, or as the discoverers, a party of hnntera, express it, "the mountain is now an island, as lt were, surrounded hy an almost perpendicular wall of rock ahout 100 fset in hight." The noise made hy the sodden sinking of this mass of rock and trees was heard sevsral miles away; hut until the discovery hy the party alluded to, no one knew whence the noise procesded. The locatlon is ahont three miles from "Laird's" on the Coos Bay wagon road.

A PHOTOGRAPHIC MARVEL.—One of the wonders of astronomy, and photography as well, is fonnd in the fact that after an exposnre of 33 minutes, the same instrnment which renders visihle to the human eye stars of the fourteenth magnitude, whioh in the entire heavens would register ahout 44,000,000 of stars, shows to the photographio eye 134,000,000, and on an exposure of one hour and 20 minutes would throw hefore the astonished gaze of the hsholder a luminous dnst of 400,000,000 stars. Never hefore in the history of hnmanity has man possessed the power of penetrating so profoundly into the depths of the infinite.

LIGHTING A MATCH BY STEAM.—An interesting experiment is sometimes tried with dry high-pressure steam issuing at a jet, which is rather astonishing. If n common matoh head is hel l in the invisihls portion of the steam jet, close to the nozzls, it at onoe lights, and the fact seems oonvincing as to complete dryness, as the faintest moisture would prevent ignition even at the highest temperatnre. This experiment proves dryness of the steam at the point of contact, hut if throttling exists hehind the jet, the steam snpplied by the hoiler may he in itself wet and dried hy wire drawing.

VARIATION IN DIAMETER OF TREES.—The diameter of trees varies not only from summer to winter, but from day to day. They are larger from noon until twilight next morning than from twilight to noon; they are smaller ln winter than in summer. Watsr and the sap of tress expand not only in proportion as they rlse ahove, but also as they go below the freezing point. Low temperature as well as high promotes evaporation, and the trees evaporate from their branches in winter, and so the ooldsr the weather the more they shrink.

WHITE-PINE BOARDS are said to he now ohtained hy redncing small trees and limhs of clear wood to pulp and pressing them in molds of any desired size.

A LUMINOUS PROJECTILE to he fired from a gun is the idea of a Russian officer. He claims great usefulness for discovering the movements of hostile vessels in a contest at night.

Good Health.

Injuries and Diseases of Nerves.

Nerves must be renewed through the medium of the nuclei which are in the inner side of the sheath discovered by Schwann. These fibers receive impressions and expend stimulus. The process of degeneration in a nerve is first a destruction of the myeline, multiplication of the nuclei and loss of continuity of the axis cylinder. There are not, as previously supposed by some, a special set of nerves which have as their function the creation of trophic conditions; the motor and sensory nerves are of themselves able to produce such a condition.

The return of sensibility to a part of the body supplied by a nerve which has been cut quite through does not indicate positively that the nerve has been reunited; the power of muscular action and other evidences are also required. When nervous power has been lost and partially restored, hope must not be abandoned, even if progress is slow, because months may be required for the reoperating process. Feeling generally returns sooner than muscular power. Nerves which have been injured may have pieces taken out and the sound end stretched till they meet, when they will reunite. Even nerve-grafting according to this author may be possible.

No benefit has been conferred on victims of St. Vitus dance by surgical experiments on the nervous system, but when epileptic fits occur, because of an injured nerve, these fearful spasms have been stopped by dividing the injured nerve between the injured part and the higher ganglion. Tetanus is not found to be caused by injury to the nerves. The best cure for facial neuralgia is found to be nerve-stretching, and is much better than cutting the nerves. —*Journal of Anatomy*

Poisonous Character of the Oleander.—A German paper says: It is perhaps not generally known that the leaves of the beautiful and gorgeous oleander are endowed with extremely poisonous properties, and that injurious effects may follow the cultivation of the plant in inhabited houses. The poisonous character of the plant is mentioned by Pliny, and recent investigations have shown that the old Roman naturalist was right. In Madrid, a few years ago, several people were poisoned by eating game which for some reason had been roasted with oleander leaves. In the southern parts of Spain and Italy, the grated bark is used as poison for rats, mice and vermin, and places where the oleander grows in abundance are considered as unhealthy as the terrible fever swamps, and are shunned by the people. In Northern Africa, where the oleander grows luxurfantly and adds a wonderful charm to the banks of every stream, it is not tolerated near human habitations, and in some districts its cultivation near houses is prohibited by law. It is a significant fact that the flowers of the oleander are shunned by bees. As the oleander is very common in California, the children should be carefully warned against it, or, what would be better, train it into a tree and prune high enough to keep the leaves and flowers out of the reach of little fingers.

The Human Breath a Poison.—At a recent meeting of the Academie des Sciences, Prof. Brown Sequard referred to some experiments he had conducted with a view to determine what, if any, were the toxic effects of the human breath. In condensing the watery vapor coming from the human lungs, he obtained a poisonous liquid capable of producing immediate death. This poison is an alkaloid (organic) and not a microbe, or series of microbes, as might have been imagined. He injected this liquid under the skin of a rabbit, and the effect was speedily mortal. The animal died without convulsions; the heart and large vessels were engorged with reddish blood, contrary to what is observed after ordinary death, when the quantity of blood is moderate and of a dark color. In conclusion, this eminent physiologist said that it was fully proved that respired air contained a volatile toxic principle far more dangerous than the carbonic acid, which was also one of its constituents, and that the human breath, as well as that of animals, contained a highly poisonous agent.—*Medical Press.*

The Sea Safer Than Land.—It may be a surprise to many to learn that statistics prove the sea to be safer to live on than land. The death rate of sailors in the British merchant marine is under 12 per thousand; the loss of life by shipwreck is about a quarter of this; in fact, there are more lives lost among miners from accident than among sailors, and many more among railway employes.

Dislodging a Leech.—A man in Portland, Wash., recently swallowed a leech while drinking from a hose. It took hold at once and for some days nothing could dislodge its hold. An old army surgeon was consulted who settled the case effectually. He put the patient to bed and kept him full of whisky for three days, when the leech got soaked and let go its grasp.

Recovering Sight.—Capt. Williams of Jeffersonville, Ind., 20 years blind, is recovering his sight. He thinks the glare in his room of an electric street light has something to do with the recovery.

Useful Information.

Is It Damascus Steel?—The Rademan-Telford Steel Company of Louisville, Ky., are continuing to make experiments with their new process, says the *Age of Steel*. Their recent experiments have been chiefly with laminated steel. Two or more sheets of steel treated by their process, with iron sheets sandwiched in between the steels, have been welded together in one heat. After being taken from the fire, it requires a great deal of force to separate the layers, and after they have been rolled once, the welding is so firm that it is quite impossible to separate them. The Hall Safe & Lock Company have experimented with the Rademan-Telford steel, and are said to pronounce it superior to their own laminated steel made at a great expense. The Rademan-Telford steel, after treatment, is very soft, and holes are easily punched in it; but after tempering, it is almost impossible to drill a hole into the sheets with the finest tools made of Mushet steel. The tempering is effected by heating the iron once and then immersing it in cold water. Specimens of the tempered Rademan-Telford steel were submitted to the Navy Department, and naval officers say that the process seems a re-discovery of the lost art of making Damascus steel.

The Oldest Drummer.—The oldest traveling man in the country, Mr. J. C. Page, started out in 1852 with half a dozen shoes in an old fashioned handbag. He sought his first order from a former employer in Montpelier, Vt., who listened to the youthful and ardent commercial traveler and then exclaimed: "Why, boy, do you think you can sell shoes by samples?" The youth thought he could. After a mature deliberation the merchant remarked: "Well, Joel, I don't believe you would deceive me; you can send me a box of those shoes." To any one who has not watched the rapid increase in the number of commercial travelers of all classes every year this story must prove interesting. That a vocation employing hundreds of thousands of persons every year, and with hundreds of millions of dollars invested, could grow up during one man's lifetime almost surpasses belief, says the Kansas City *Times*. The business has grown from the single venturesome Yankee boy of 1852 to 200,000 in 1880. It is expected the present census will swell that number to fully 400,000.

Lions and Locomotives.—The lions of India appear to be going the way of the great bustard and dodo, says the London *Daily News*, and the reason is found in the extension of railways, for the monarch of the forest entertains mortal antipathy to the smoke and screams of locomotives. Within the memory of many persons lions were common enough in Rajputana, and even now the roar of one may be heard occasionally in the wildest part of Central India; but the new railway from Nagpur is now being constructed through this country, and this is practically a notice to quit served upon the few remaining lions in the central provinces.

Lemons Are Used for Soap in many countries where they grow. When, for instance, the men and women of the West Indies want to wash their hands, they squeeze the juice of a lemon over them briskly in water until they are clean. There is an acid in the lemon similar to that used in soap, and in countries where oranges grow in great plenty, country gentlemen use the cheapest kind for blacking their boots. The orange is cut in two and the juicy side of one-half is rubbed on the soot of an iron pot and then on the boot. Then the boot is rubbed with a soft brush and a bright polish at once appears.—*Sacramento Union.*

Wood Brought to a Mirror Polish is coming into use for ornamental purposes in Germany, and has this advantage, that, unlike metal, it is not affected by moisture. The stuff is first treated with a bath of caustic alkali for two or three days, at a temperature between 164° and 197° F. Next comes a dip in hydrosulphate of calcium, for from 24 to 36 hours, after which a concentrated solution of sulphur is added. After another soak in an acetate of lead solution, at 95° to 120° F., it is thoroughly dried and polished with lead, tin, or zinc, as may be desired, when it resembles shining metal.

The New White Lead Process.—The new apparatus invented in Glasgow, Scotland, for the manufacture of white lead consists of three distinct parts, namely, a furnace, a condenser and a washing machine. The lead is untouched by hand, the whole of the process being conducted by machinery. The manufacture is kept going by shoveling into the furnace a quantity of lead ore, and that is converted into white lead, washed and dried, in three hours, as compared with four months by the old system, and the price of sulphur of lead production is reduced nearly two-thirds.

New Soldering Mixture.—A new and effective soldering mixture has been invented and patented by Mr. C. N. Waite of Littleton, N. H. It consists of lactic acid and glycerine, the best proportions being one pound of each of these substances, with eight pounds of water.

To Find Any Color Contrast.—The following is a good rule to find the contrast of any color: Cut out a circular piece of the petal of any flower, and put it on a white paper, look at it fixedly for a few seconds with one eye, then look off the color on to a piece of white paper, and you will see a bright ring of another color; that ring or circle is the right complementary color or contrast to the color in the petal.

Paper or Pasteboard may be rendered waterproof as follows: Mix four parts of slaked lime with three parts of skimmed milk, and add a little alum; then give the material two successive coatings of the mixture with a brush, and let it dry.

The Oyster is one of the strongest creatures in proportion to his weight in existence. The force required to open an oyster is more than 1300 times its weight.

The Builder.

Slow Burning Construction for Dwellings.—For cheap houses, or houses usually described as being "of moderate cost," it may be that there is not yet any method of slow burning construction that can be afforded. Some day there will be, but the time has not perhaps arrived when the economy which is absolutely required in such cases can be combined with the security which would be highly desirable. But no man who builds, or has built for him, a house costing $10,000 or upward, has a right to neglect any means which science has brought to light for the prevention of fire or for retarding its progress in the event of its breaking out. On this subject *The Standard*, an insurance journal, has the following timely remarks: It seems to us that the slow burning construction required in factories by the mill mutuals might be transferred to wooden dwelling-houses, as far as the floors are concerned, at least. The arrangement of widely spaced, heavy beams, with thick plank flooring, is susceptible of very tasteful architectural treatment, and would do away with the numerous horizontal flues formed by the usual spacing of joists. The plank floors could be deadened with a layer of asphalt, snugly held in place underneath by sheathing, and this layer would also prove a barrier to the rapid spread of fire. The walls and partitions might also be constructed of fewer but heavier timbers, with thick coats of plastering keying between laths, but slightly raised from the sheathing. Such a structure, we think, could oftener be saved from the flames than those constructed by the usual method.

Iron and Steel for Wood.—It appears that special attention is being paid in France and England to a more general substitution of iron and steel for wood wherever practicable in manufactured articles, such, for instance, as building materials, boxes and packing-cases, barrels and casks, carriages, carts and other vehicles, furniture, fencing, railway work, sheds, signal-boxes, telegraph poles, etc. In France there have recently come into use hollow iron window frames and doors which are said to be light and strong, and of far greater durability than could ever be expected of wood. There is no reason, too, it is thought, why corrugated barrels of iron and steel should not be used for liquors, since milk and preserved fruit and other articles are kept in cans. Steel is finding much favor among carriage builders, but there is still much prejudice against the metal being used in the manufacture of furniture. The general adoption of steel sleepers is warmly advocated by some, as is also the employment of iron and steel in the construction of railway cars; and the erection of wooden sheds, signal-boxes, etc., by railway companies as at present, might, it is urged, be profitably and economically substituted by steel.

The Plain Design Is Best.—In house-building, only a high degree of artistic talent, which costs money and must have plenty of money at its command, can be safely employed in elaborate ornamentation. On this point the Philadelphia *Real Estate Record* quotes from an exchange the following sound advice: "One of the chief reasons for the failure of cheap houses to look well is the fact that they are overloaded with ornaments. If those who wish to build cheaply would be content to build plainly, the results would be more satisfactory to the eye. The same fault is noticed in cheap furniture. It is always disfigured with fancy turns and machine carving, while to find a piece of plain, substantial finish, one must look at the high-priced goods. Too many men only able to build a cottage load it with weak imitations of the handsome decorations of the palace, and the result is thoroughly inharmonious. In the cheap house let plainness of construction reign from foundation to gable. Let the ornamentation be not in the woodwork, but in the painting. Then the effect may be whatever desired, and may be changed at the pleasure of the owner."

Elevator Speed.—The competition of builders and experts has succeeded in accelerating the speed of elevators until, in some instances, it has reached 500 feet a minute. A few years ago 200 feet was considered a very rapid movement for an elevator. It is very encouraging to hear the opinion expressed by experts that there is not much danger in the modern swift running elevator when it is carefully managed and looked after by an expert.

Engineering Notes.

A Civil Engineering Era.

This is the greatest hour for the civil engineer that the world has ever seen. Tremendous problems everywhere are being thrust upon him for solution. Take the World's Fair for 1892. The discussions pertaining to it are of consuming interest to civil engineers. The paramount questions of drainage, the lake front, the lowering of the railroad tracks, construction of viaducts, and the erection of phenomenal towers, are all directly in the line of the profession. Not one of these is a project of small import, but all of the propositions call for the exercise of the very highest mental qualities in the calling.

The drainage system alone will call into use the varied artistic, mechanical and scientific knowledge of the best men who write "C. E." after their names. It involves a knowledge of the topography of every foot of ground in the city and far beyond its limits. It proposes a network of sub-waterways and an amount of excavating which is little less than stupendous. The disposition of the excavated material alone presents a problem, which is possibly answered, however, in the probability that it may be needed as filling for the fair grounds proposed on the lake front.

Another question connected with drainage, and one which is figured in with the calculations of far-seeing engineers, is the archlag of the river and the unification of the south, west and north divisions.

The World's Exposition, its grounds, its structures and its sanitary features will call high engineering talent into play wherever the site may be located, and particularly so if the grounds are to be made, as it now looks, "from the waters of the lake."

The subject of grade crossings in the city, while not so much discussed in public, is deemed of the utmost importance in engineering circles. So sure are the gentlemen of the profession that it is a great coming question that the Society of Western Engineers has taken time by the forelock and is gathering data with the greatest care and at large expense, showing the course and levels through the city of every railway—main, switch and stub. The ultimate demand, it is thought, will be to have the tracks lowered to within four feet of city datum, and the whole sewerage system and the viaduct arrangements, so far as inaugurated, made to correspond to the requirements of the new track level.—*Western Machinist*

The Great Pennsylvania Ship Canal.

The great work of connecting the Ohio river and the city of Pittsburg with the Great Lakes by a ship canal is now in a fair way of being fully realized within a reasonable period of time. It will be one of the most important works of internal improvement ever undertaken in the country. At a meeting of the commission held three weeks ago, its engineer, John M. Goodwin, in making his report of the work done during the past month, said that, having carefully observed the conditions existing along the Shenango line, he sees nothing amounting to a very serious obstacle to the construction of a ship canal on the route in question, and he is of the opinion that the result of the straightening and material deepening of the Shenango river and the deepening of the Beaver, which will be effected in any proper construction of such a canal along these streams, and the maintenance all along the 51 miles of valley, extending from a point three miles above Sharpsville to Rochester, and thence along the right bank of the Ohio river to Pittsburg, will be a grand waterway, bearing not only the qualities of a great commercial highway, but also those of a beautifying and sanitary and power-supplying river. He believes that the region in question thus endowed will become the scene of industrial and social development, exceeding in commercial importance and in all desirable qualities and conditions any heretofore anywhere attained. Mr. Goodwin, in concluding his report, holds that the projected waterway should meet with no opposition from railroads. He says that the valuable and indeed absolutely necessary agency of the railways in the matter under consideration is of course fully taken into account in his view of the subject. He fully believes that the traffic incident to the construction of the canal would largely increase the business of the railways of the districts adjacent to the canal, and that the development following the establishment of the canal would induce a railway traffic in the regions affected by the canal far in excess of any otherwise possible.

Niagara Will Surely Be Harnessed.—So it would seem, at least. The Cataract Construction Company, which proposes to build a tunnel around Niagara Falls, and to run machinery in factories by means of water-power, has signed contracts with the Niagara Falls Power Company. The contracts are not to take effect until some minor difficulties are overcome. By this it may be understood that some people still refuse to sell their land to the company. But this is likely to be overcome. The Cataract Construction Company is an organization formed under the laws of New Jersey. Its officers are New York men. Edward A. Weeds is president, F. L. Stetson, vice-president, and W. B. Rankine, secretary.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Percussion Table for Dressing Ores; Three-Compartment Jig for Dressing Ores, 33. Map of San Bernardino County, 92-93.
EDITORIALS.—Mineral, Not Agricultural; Jigs and Percussion Tables, 83. Passing Events; Our Correspondents; The Molders' Strike; The Foundry Business; San Bernardino County Mines; Beach Sand Mining; Academy of Sciences; The Mining Bureau Museum, 90. On the Determination of Iron; New Stockyards and Packing Houses, 91.
CORRESPONDENCE.—The Gold Belt of Northern California; The Accident at Hayden Hill Mines; San Bernardino County, 84. Mines and Mills of Shasta County, 85. Gold in the Cascades; Quicksilver Mines, 91.
MECHANICAL PROGRESS.—Compound Locomotives in Germany; Band Saw for Metals; Saving of Dead Weight by Use of Steel; Discovery of Novel Properties in Cast Iron; American Stoves; Mechanics as Inventors; A Spring Propelled Vehicle; Government Tests of Aluminum Bronze; American Scissors in Sheffield, 88.
SCIENTIFIC PROGRESS.—Tanning by Electricity; In Aid of Science; How We Look at Things; A Curious Phenomenon; A Sunken Mountain; A Photographic Marvel; Lighting a Match by Steam; Variation in Diameter of Trees; Miscellaneous, 88.
GOOD HEALTH.—Injuries and Diseases of Nerves; Poisonous Character of the Oleander; The Human Breath a Poison; The Sea Safer than Land; Dislodging a Leech; Recovering Sight, 89.
USEFUL INFORMATION—Is It Damascus Steel? The Oldest Drummer; Lions and Locomotives; The New White Lead Process; Miscellaneous, 89.
THE BUILDER.—Slow Burning Construction for Dwellings; Iron and Steel for Wood; The Plain Design is Best; Elevator Speed, 89.
ENGINEERING NOTES.—A Civil Engineering Era; The Great Pennsylvania Ship Canal; Niagara Will Surely be Harnessed, 89.
MINING SUMMARY—From the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Wyoming, 86-87.
MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 98.
MARKET REPORTS.—Local Markets, Eastern Metal Markets, 98.

Passing Events.

The decision in the Francoeur vs. Newhouse case rendered this week, involving the question of mineral and agricultural land on railroad grants, is one of the most important to the mining industry ever given in this State. It was decided in favor of the mineral claimant, which will be a great relief to some hundreds of mine-owners in California whose property was in danger of practical confiscation.

The events in connection with the foundry strike have been somewhat exciting during the past week, blood having been shed and more or less shooting having occurred. More police have been stationed in the iron district of the city so as to prevent further trouble.

The plan of executing criminals by electricity, for the first time tried on the murderer Kemmler, in New York, is not likely to find further favor, judging from the experience in this case. The man was killed, but the death was apparently not instantaneous and the current had to be turned on a second time to complete the work.

The renewal of the order of the Government authorities to reserve from location the tracts of the *Sequoia Gigantea*, or big trees, in this State is an excellent thing. There are not many groves of these giants in the world, and there is plenty of timber in the State without destroying such magnificent trees.

San Bernardino County Mines.

With this number of the PRESS is printed as a supplement a sketch map of a portion of San Bernardino county, showing the important mining districts and other features, including town, railroads, springs, wagon roads, etc. With this is also an outline section showing the relative hights of the mountain ranges and peaks.

On the bottom of the map is printed a list of the prominent mines of the county, developed and in process of development, producers and non-producers, but susceptible of being made dividend-payers with the assistance of capital. The geographical position of these mines is so indicated that their location is easily fixed on the map. There are on the list 157 mines carrying the ores of gold, silver, copper, lead, antimony, iron, zinc, etc.; two marble quarries, two granite quarries, three sandstone quarries, one salt-bed and one borax measure. This map and list of mines were prepared for the MINING AND SCIENTIFIC PRESS by James H. Crossman, who is writing for us a series of articles on the resources of the county, one of which, relating to the mountainous regions, appears on another page.

It was not the intention in this case to make much more than a mere outline map, correct as far as it goes, but lacking details of a more complete one now being made on a larger scale by Mr. Crossman. This will, however, serve the purpose of showing the mining districts and locations of the prominent mines of the county, together with such features as give the general reader an idea of the section of country it represents to a fuller extent than any other map yet printed as far as we are aware.

San Bernardino is the largest county in the State and many of its resources are entirely undeveloped. It already produces more silver than any county in California, and its citrus fruits have the widest reputation for excellence. Such is the range and variety of the region that the miner and horticulturist both flourish to each other's benefit and to the benefit of the State itself. The articles describing this county are written by Mr. Crossman from notes taken while inspecting the county during several visits. He leaves this week for another tour through the county to gather fresh material.

Beach-Sand Mining.

On the ocean-beach near San Andreas, Santa Cruz county, about 20 miles from the city of Santa Cruz, is now in successful operation a machine for saving the gold in the black sand and concentrating, if necessary. They have been experimenting with the machine for some time on the beach, and are now confident that it saves all the gold and handles the large amount of ten tons an hour. The machine is worked right on the beach and the ocean water is used. The gentlemen who work this machine understand their business and are preparing to extend their operations.

Besides the ocean or outside beaches, there are numerous inland "beaches" or deposits of this sand. A company has been formed in Santa Cruz under the leadership of Jesse Cope, Esq., an old-time miner and now a successful merchant of that town, to operate the Leonard farm near San Andreas. All necessary machinery is already on the ground, and the gold-saver will be completed this week and work at once begun.

The general agency of this new gold-saving machine has been given to F. H. Hausman 320 Sansome street, this city, who will give any desired information as to cost, etc.

The Foundry Business.

Buyers of machinery and other iron work should better realize that notwithstanding there is trouble in this city with the striking molders, the manufacturers are in a position to do work as usual. Many orders are being sent East for work that should be done here. The foundry-owners have brought men here at great expense and trouble, to take the places of those who have struck, and can undertake any kind of a job now just the same as they could before the strike commenced.

The San Francisco foundries are the largest manufacturing establishments we have in California, and should be liberally patronized by all who want anything they can produce. It is unjust to them to send away work which they can do here. Those having orders to fill ought to consider twice before having work done elsewhere. We are assured by the foundrymen that they are now able to do any kind of work required of them. Still, there is lack of orders, and the foundry and machine-shop business is very dull indeed.

The Molders' Strike.

The trouble between the foundrymen and molders in this city reached a point this week when more blood was shed and the second victim of this strike went to his account. This time the evidence leaves no doubt about the man who was shot being one of the strikers. He entered a street-car with a companion to "persuade" a non union molder who was riding there and during the argument struck the young man, who, to protect himself from injury, drew a pistol and killed his assailant. The name of the non-union apprentice molder was Walter Rideout and that of the striker Henry A. Siebert. Rideout was an employe of the City Iron Works at North Beach and the other man a member of the Molders' Union.

About the same hour, on the same evening (Saturday), two non-union molders were attacked on Howard street by a number of strikers, and pistols were again used but no one was killed. Several of the men were, however, injured. Pistol-shots have also been fired at the men in the windows of another foundry.

Since these acts of violence the number of policemen in the foundry district has been increased and attention is being paid by the authorities to preserve order. Arrests are being made of persons who have made threats or intimidated others, and the "pickets" will not be permitted to congregate in groups around the foundries but must "move on" or be subject to arrest.

The methods adopted by the strikers have greatly prejudiced their case in the eyes of the public. There is no objection to men refusing to work under certain conditions, or trying to gain their points by any lawful methods, but there is decided objection to their using force and interfering with the business or work of other people. These so-called "pickets" should be compelled to go away from the vicinity of the iron works, and the foundrymen ought to be protected in conducting their legitimate business.

It is a disgrace to a civilized community when men cannot go peaceably about their occupation without having to arm themselves and seek police protection, but the frequent assaults show that these things are necessary in the iron districts of the city. Some very stringent measures should be adopted against the lawless element among us, whether as individuals or banded together in the name of a labor union. The largest manufacturing establishments in California are the iron works of San Francisco, yet they are obliged to call upon the police to protect their men in going to and from their homes. Nearly all trades and manufactures are injured. Such a state of affairs will not long be tolerated.

Our Correspondents.

The PRESS feels rather proud of the many correspondents it has represented in its pages in these days. Every issue of the paper contains several communications from men who have something to say and who say it in a manner that every one can understand. These correspondents are mostly practical men, and others in their lines can learn something by reading their letters.

In this number of the paper, for instance, are several letters from men actively at work in the mining districts of the coast. They write on subjects of interest to miners elsewhere. The very practical description of the conditions of finding gold in gravel from the pen of Mr. J. F. Talbott, now being continued in a series of articles, will be found of value to gravel miners and those who have made a study of the subject of the auriferous river-beds found in our lava-capped divides. The articles by Mr. Crossman on the mineral resources of San Bernardino county, besides their general interest, give many details of the mining conditions in that section of the State. This week, as last, he deals with the mountain districts of the county. The description of the reduction works and process of the Calumet Co. in Shasta county by one of our traveling correspondents is of the greatest interest to those engaged in milling gold ores. Mr. Hermanson describes a new method of the determination of iron; Mr. Blackburn, the Cascade gold-mining region; and another correspondent, some of the quicksilver mines of California.

This week, as for some months past, the PRESS prints many articles from contributors which add much to its value to mining men. We are always glad to add to our list of correspondents, however, and shall be pleased to receive letters from others who may have anything of interest to contribute to the general stock of knowledge.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening, President H. W. Harkness in the chair. A small shark of the man-eating species, the first of the kind ever caught in this bay, was presented to the museum. It is a rare fish for such northern waters as these, though a few have been seen at San Diego.

Prof. Gustav Eisen, who has recently returned from a trip to the big-tree forests of the Tule and Kaweah rivers, called the attention of the Academy to the magnificent groves of the *Sequoia Gigantea* along these rivers, which are now being ruthlessly destroyed. On the Tule river are to be found the largest number of big trees to be found anywhere in the State. A very large portion of this marvelous timber has been purchased by private parties, who are now cutting down the trees as fast as possible. There are hundreds of these monarchs of the forest 20 and 30 feet in diameter which have been cut down and only a small portion of the lumber in them utilized; the rest has been left to rot on the ground.

Professor Eisen saw the stump of a tree near the Tule river, Tulare county, that had just been felled. It was about 33 feet in diameter and the hight was not less than 250 feet. The man who cut the tree down sold it for $60. It was calculated that from the top of the tree 60,000 shakes would be made. A part of the trunk has been secured for exhibition at the World's Fair. In this same region there was cut a monster tree 41 1-3 feet in diameter and 250 feet high. A part of the trunk of this tree was sent to the Centennial. The rest of the tree was left to rot. Professor Eisen said it was a sad sight to see such great trees destroyed. The stump of the tree which was sent to the Centennial contains 6126 rings, indicating in all probability that the tree was that many years old.

There are still many tracts of land covered with huge redwoods which the Government still possesses, and there is now an effort being made to have these groves perpetually reserved from sale.

On motion of Professor Eisen the Academy instructed the President to appoint a committee of three to draft a memorial to the Secretary of the Interior requesting that official to do everything in his power to save the remnant of the fast-disappearing big trees. Gustav Eisen, J. R. Scupham and W. S. Chapman were appointed such committee.

SAN BERNARDINO COUNTY MINES.—The following corrections should be noted with reference to the list of mines printed on the margin of the map issued with this number of the PRESS. The Garfield mine is in Township 10, Range 1 E., instead of 2 E.; Occidental, Nos. 1 and 2, are in Range 1 E.; Olio in Range 1 E.; Hanover in Range 1 E., and Thunderer in Range 2 E. The following additional mines should also be noted: Oriental, Township 10, Range 1 E.; and the Dunderberg, Gohlin, Dragon, Veto and Maiden, all in Township 10, North Range, 1 E.

CHARLES C. GRAHAM, Charles Hill and Ed. Holden of Philadelphia are in Salt Lake City. Mr. Graham owns the Philadelphia Smelting and Refining Works at Pueblo, Colorado, while the other gentlemen are associated with him. They are in Utah for the purpose of purchasing the right to use the Russell process of treating ore by infiltration in Colorado.

THE Ellensburgh (Wash.) *Capital* says many settlers in the Big Bend country have been driven away by the ravages of squirrels that swarm in countless numbers in that region.

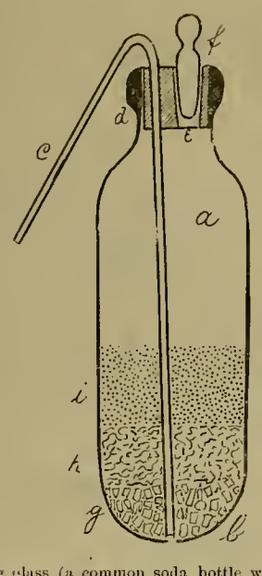
On the Determination of Iron.

[Written for the PRESS.]

Mr. Clemens Jones has contributed an elaborate paper on the determination of iron by titrating with permanganate of potassium (Method of Marguerite), published in the Transactions of the American Institute of Mining Engineers, Vol. XVII, pag 111. The old method of reducing ferrisulphate to ferrosulphate requiring some time and much patience, Mr. Jones has devised an ingenious apparatus for the rapid reduction of ferrisulphate by filtering the solution through pulverized zinc.

May it be justified by the importance the subject has for the metallurgist to publish the way the author uses to perform the same operation, dispensing altogether with a vacuum pump and that expensive machinery, invented by Mr. Jones, substituting for it a little automatically working arrangement, which, owing to its simplicity, will be fitted up by any assayer or student.

In the accompanying sketch is *a* a bottle of



strong glass (a common soda bottle will do), with a round bottom *b* from which the last drop of fluid can be removed by the siphon *c*.

The stopper *d* has a second boring e to be stoppered by the stopper *f* and wide enough to allow the easy passing of the tip of a 100 c. c. pipette.

The bottom of the bottle is covered with small pieces of broken glass *g*, over which is spread a layer *h* of glass wool or fine fibers of asbestos, carefully cleaned. This mineral filter will support the layer *i* of pulverized zinc, and it ought to be dense enough to retain any particles of the latter.

The bottle being filled up as indicated and the stopper *d* having been secured, so as to fit tightly, 100 c. c. of diluted sulphuric acid are transferred to it with the pipette. It will suit best to make up in a Winchester the standard solution of sulphuric acid of 2%, to be used throughout the operation, or of 1% in case a 200 c. c. pipette is used.

The fluid will rest upon the zinc, prevented from penetrating it by hydrogen, but as soon as the hole *e* is stopped tightly with the stopper *f*, the growing pressure of the gas forces the fluid through the layer of zinc *i*, that of glass wool or asbestos *h* and out through the siphon *c* into a spacious beaker placed beneath. The fluid in the beaker, being diluted with water (distilled and otherwise clean water ought to be used throughout) and acidulated with sulphuric acid (standard solution), ought to be titrated immediately with permanganate of potassium and the same operation ought to be repeated with new quantities of 100 c. c. sulphuric acid (standard solution) each, until the result of titrating appears constant, this being necessary because the zinc contains iron, the amount of which will be fixed after a few titrations, thus allowing to make a close correction for each assay.

The way a correction for iron contained in the pulverized zinc is to be made, of course, will depend upon the accompanying constituents in the solution of sulphate of iron to be titrated and ought to be calculated by the manipulating chemist according to the case. Mr. Jones dwells at length upon the impurities of zinc and gives a great number of examples with the correction he applies when titrating, but he never tells how he gets that correction.

In order to prevent this uncertainty from being transferred to the method here expounded, we will track the course of operating for the simplest case. At first we must standardize our solution of permanganate of potassium, which we have so far diluted that it will just allow using the plunger in the burette. We take a piece of fine, soft and well cleaned iron wire, weighing about as much as the iron in our assay; we make the correction for carbon in the weight of that wire (about $\frac{1}{2}$ %) and dissolve it in 100 c. c. of our diluted sulphuric acid. After dissolving we dilute to 300 c. c., well mixing in a stoppered shaking bottle, and titrate 100 c. c. after passing it through our reductor. This done, we immediately pass 100 c. c. diluted sulphuric acid through the reductor and titrate it, repeating this until we get a constant reading. Now we may repeat the operation with a new 100 c. c. of the solution of iron and we ought to find exactly the same result. All readings noted, we proceed to figuring the titre. Assuming we got a as the constant number of c. c. permanganate of potassium when titrating repeatedly 100 c. c. diluted sulphuric acid, as required before, we know that a will represent the iron that is extracted from the zinc by 2 grm. H_2SO_4 when passing through the reductor. Assuming the titration of 100 c. c. of our solution of iron consumes b c. c. permanganate of potassium and that when titrating afterward the diluted sulphuric acid as prescribed, we are using at first d c. c. and then e c. c. before we arrive to the constant number of a c. c. permanganate of potassium, then will b + (d—a) + (c—a) be the exact number of c. c. permanganate of potassium, consumed by titrating 100 c. c. of the solution of iron used for standardizing, the last two members of the sum belonging to that iron, intercepted by the filtering layers of the reductor.

Supposing the simplest case of an assay for iron, we suppose we got our iron, parted from other metals, precipitated by ammonia; then we dissolve it in 100 c. c. of our sulphuric acid, containing 2 grm. H_2SO_4. We dilute the solution to 300 c. c., pour it into the mixing bottle (this being necessary as the ferric sulphate by its gravity settles to the bottom), shake well and titrate 100 c. c. after passing it through the reductor. Then we repeat titrating by 100 c. c. sulphuric acid at a time unto the constant number of c. c. permanganate of potassium. After this we make the controlling titration with a new 100 c. c. of our solution. Should there appear a difference in the results, it will prove a mistake or a leak in the apparatus, which having been repaired, we may use the remaining 100 c. c. of the solution for checking the results first obtained.

Let x be the number of grm. Fe we are determining in 100 c. c. of our solution; assuming we used f c. c. permanganate of potassium when titrating the same and further on g c. c. and h c. c. by titrating repeatedly 100 c. c. diluted sulphuric acid until we arrive to the constant number a, then will f + (g—a) + (h—a) be the number of c. c. permanganate of potassium, satisfying 100 c. c. of the solution of iron. As we have already standardized the permanganate of potassium, we will find the number of grm. Fe resulting from the titration. Be it p, then in the equation p = x + y, y is the wanted correction, that is the number of grm. Fe extracted from the zinc in the bottle while reducing the solution.

Using quantities as those before recommended, the reduction is always complete and the fluid drawn from the reductor ought to be neutral, unless the reductor be out of order. (The testing with sulphocyanide of potassium requires some discretion; you may see no coloring when mixing the two drops upon a porcelain plate, but after drying there will appear a pure white scale with a fine red contour, betraying the ferricum.)

Consequently y grm. Fe is that iron extracted from the zinc by an excess of H_2SO_4 over that consumed in oxydizing x grm. Fe to $FeSO_4$, when we took 2 grm. H_2SO_4 contained in 100 c. c. of our standard solution. Substituting antomic weights, we find $(2-\frac{98}{56}x)$ grm. H_2SO_4 to be that excess.

Be *q* the number of grm. Fe that correspond to a c. c. permanganate of potassium in titrating, then obviously $(2-\frac{98}{56}x) : y = 2 : q$, which equation together with p = x + y give the final value of x.

July, 24, 1890. OSCAR HERMANSON.

New Stockyards and Packing-House.

It now seems pretty certain that mammoth stockyards and packing-houses will be established at Biden Station, in San Mateo county, where both water and rail transportation are available. The company has purchased there some 3000 acres of land at a cost of $776,000

The principal parties engaged in the transaction are Nelson Morres, a large holder of Atlantic & Pacific railroad stock; Philip D. Armour, who, in addition to his stockyards and packing establishments, is also a large holder of Atlantic & Pacific securities; Hammond & Co., Swift & Co., and P. D. Iler, the millionaire pork-packer of Omaha, who has been the financial agent of the syndicate in San Francisco.

The 3000 acres purchased will be divided as follows: Twelve hundred acres will be used by the different stockyard corporations already organized in this city, and the other 1800 acres will perhaps be used for the shops and roundhouses of the Atlantic & Pacific railroad, which will be extended from Mojave on to San Francisco with all possible speed.

The following companies have been organized to operate the immense establishment: The Stock Yard Land Co., capital $2,000,000; the Avstory Co., for butchering, with large chilling and freezing houses, capital $300,000; the Stockyards Banking Co., capital $250,000; and lastly, the Stock Yard Co., capital $1,000,000. The last company includes the stockyard propsr. Millar & Lux will remove their butchering business to the new yards.

The butchering business will undoubtedly be transferred entirely to the new company'e establishment, thus ridding San Francisco of a great and dangerous nuisance. In fact, it is stated here that the company has arrangements made with all the large butchering firms in San Francisco. A thriving town will of a necessity be located at Biden, near the yards, as it is estimated that fully 4000 men will be employed in the stockyards and packing establishments, exclusive of the railroad employes, who will number at least 1000 more.

The packing company will compete not only for the coast trade in canned, pickled and packed meats, but it will secure the trade of the South seas, the Hawaiian islands, Alaska, Central and South America and China and Japan. With its advantages it can easily obtain the trade of all the countries mentioned, besides supplying the hundreds of steamers and sailing vessels which annually leave San Francisco.

Gold in the Cascades.

EDITORS PRESS:—The Cascade Gold Mining & Milling Co. is opening up some splendid gold and silver mines on Uncle Si mountain, near the Snoqualmie river, directly east of this place. One of their mines is showing up big. The ore is free-milling, with sulphurets, and there are thousands of tons of ore exposed going all the way from $18 to over $1000 per ton in gold, with some silver, some of it going over 50 ounces silver per ton. The vein of pay ore is immense. At some places it measures over 50 feet wide. The vein shows a little copper. The gold and silver is in a quartz and iron gangue. Formation, granite, porphyry and gneiss, with a little slate near by, good talc casing between the wall and ore. The talc also contains gold. Large prospects can readily be obtained all over the surface of the quartz claims. This gold comes undoubtedly from the ledge, as it is all rough and ragged-looking gold—just like that usually found around gold veins.

The Cascade Gold Mining & Milling Co. is developing its property by tunnel and will erect a No. 1 plant for treating its ore. The mines are only 2½ miles from the terminus of the Seattle, Lake Shore and Eastern railroad. Plenty wood and water. The ore can be mined and milled for $5 per ton. This portion of the Cascades between Mounts Rainier and Baker is a first-class mineral country—gold, silver, copper, lead and iron.

The writer speaks from personal observation—seeing is knowing. The day approaches and is near at hand when this grand old range will turn out its millions. CHAS. F. BLACKBURN.

Seattle, Wash.

TELLURIUM.—A dispatch from Redding, Shasta Co., dated Aug. 2, says: The stockholders of the Eureka tellurium mine are quite elevated over a new find in their shaft. After pumping the shaft out and sinking five feet, a fine ledge of gold and tellurium ore was discovered. The experts had proclaimed the mine no good, but this new discovery shows that a ledge rich in precious metal does exist. The mine is three miles from Redding.

Quicksilver Mines.

The Manhattan and Redington.

EDITORS PRESS:—Sixteen miles southeast from Lower Lake on the road leading from Morgan to Berryessa valley is the Manhattan quicksilver mine.

The principal owners, Knox and Osborne, were the original proprietors of the mine at Knoxville, more widely known as the Redington. While operating that mine as early as 1862, they began sending out prospecting parties of 10 to 20 men farther up the divide, and when a few years later on they had a good chance to sell the original mine, they moved to the present location. Tunnels are run everywhere about the hills like squirrel-holes. This firm employs none but white men—cooks and all. As they are just starting up a new furnace, it seems a very safe guess that the mine is prospering.

The Old Redington Still a Mine.

After riding two or three miles down the hill from Manhattan, we came to Knoxville and this famous mine. We chose the above heading, as it was reported not long since, in giving its output of quicksilver, that this was the "last dying kick." A. McMillan came there 16 years ago, a late arrival from Scotland, and began work as book-keeper. Conditions have favored him so that by steady industry and close, careful management, he is now proprietor, superintendent, underground foreman, furnace foreman, book-keeper and storekeeper. He showed us machinery and works with plans of mine and bodies of ore to convince us that the Redington may have a future quite as noted as its past. In addition to the mine, Mr. McMillan has 7000 acres of farming, range and timber land, and was very sorry he lost the chance last year to buy 5000 or 6000 acres adjoining him.

The old company never went more than 500 feet from their main shaft and neglected prospecting so that when they struck some low-grade ore that did not pay when quicksilver was selling at $27 per flask, and they happened to be losing in other quarters, they gave Mr. McMillan a very good chance to show his faith by his works.

Valuable Inventions.

My attention was called to the Livermore furnace and condenser. This furnace is for roasting fine ore that used to be made into adobe to prevent its clogging the draft of the old coarse ore furnace. In speaking of the improvement we understood Mr. McMillan to state that on some trials the Livermore appliances had turned out five times as much quicksilver from the fine ore as the coarse ore furnaces from a similar amount of coarser ore from same part of mine. Again we hear it reported that Mr. Osborne says that it is no trouble to roast the quicksilver out of the ore, but that the main point is to get a condenser that will save it; more than half the metal goes off in fumes. The large tract of timber that has been destroyed by fumes from the Bradford furnace gives color to this last statement.

We heard through a teamster who hauled the metal that the Redington was sending off 70 flasks per week last summer when only working 25 men. (This seems almost too good to be true.) It seems pretty clear that Mr. McMillan is remarkably certain to get his value back in labor or in silver when he pays a dollar out on the mine.

He struck a new body of ore, prospected it with a mule and whim, and has just sunk a new shaft and started a new engine. At the old shaft is a splendid plant that he will start up one of these days.

New Plan of Draughting a Mine.

This was done by Chas. Livermore and gave me a clearer idea than I ever before received of a mine. Each level was represented by a pane of glass with black ink showing shaft and tunnels and red ink to show the ore body. These panes were protected by sash made on two sides with round, wooden rods grooved and connected by little wire bolts. These rods rested in a rack that brought each one half an inch below and as much farther forward than the one above. This shows clearly the shaft and tunnels and the slopes and pitch of the ore body in each level.

If quicksilver holds its own and we see Knoxville next year, we expect to see all those cottages on the hill occupied again. The old mine is said to have yielded $5,000 000 worth of quicksilver, and we believe it is worth a dozen dead mines yet. F. S. C.

THERE are now in the Mission and Santa Paula petroleum districts, Ventura Co., 70 wells in operation. A new company will put down new wells in Hopper canyon and in the Sespe. Mr. Hutton says that prices have not advanced since last year, but that the market has greatly increased in extent and demand. The asphaltum, for example, is now sold as far East as New York, from which place an order for 2000 tons was recently received.

CERRO COLORADO MINE.—Some of the heaviest Mexican capitalists have organized a company to purchase and work the Cerro Colorado gold mine in Chihuahua and in the Batopilas mining district. This is considered the richest gold mine in Mexico. Work at the mine will be begun in 60 days.

—THE—

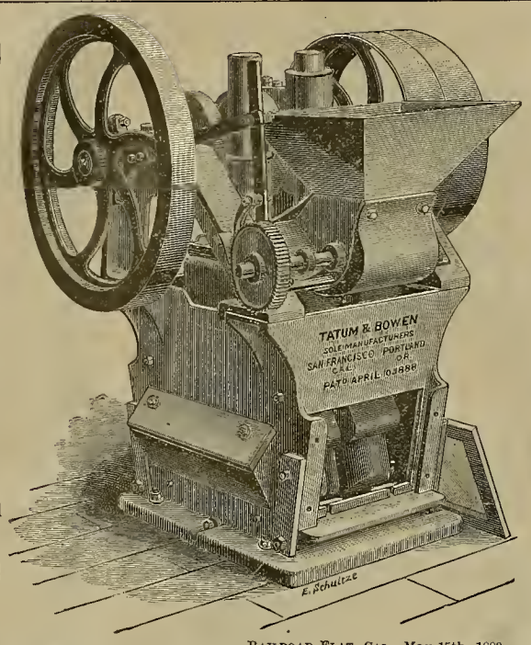
PERFECTED

DOUBLE

Economic

Quartz

Mill.



Attached to each Mill is an effective

Automatic Ore Feeder.

RAILROAD FLAT, CAL., May 15th, 1889.

MESSRS. TATUM & BOWEN, San Francisco—GENTLEMEN: I have had many inquiries in regard to the performance of your oscillating Stamp Quartz Mill, to all of which I have made substantially the following answer:

That it will crush and discharge through a No. 30 mesh wire screen, 6 tons of average quartz per 24 hours; that, compared with the common stamps, the power required to do the same amount of work is considerably less—the slipping motion of the stamps reducing the ore much faster than the drop alone can; that the discharge is good, and as to amalgamating and saving gold, my experience with it is that it is just about the same as the ordinary battery.

To the above I shall add that the new Automatic Feed attached is a perfect success. It can, in a moment and without stopping, be adjusted to feed just as "high" or "low" as desired, and can be depended upon to supply the stamps with ore exactly as they need it. This is important, as it saves feeding by hand, which cannot be considered at the present day, or the purchase of a high-priced feeder.

Considered as a convenient Mill for prospecting, or for a small mine, it fills the bill.

Yours truly, [Signed] JAS. S. REYNOLDS,
Supt. New York Mine, Railroad Flat.

The Mills as we make them now are Far Superior to the one at the New York Mine.

TATUM & BOWEN,

34 and 36 FREMONT ST., SAN FRANCISCO, CAL.,

AND PORTLAND, OREGON.

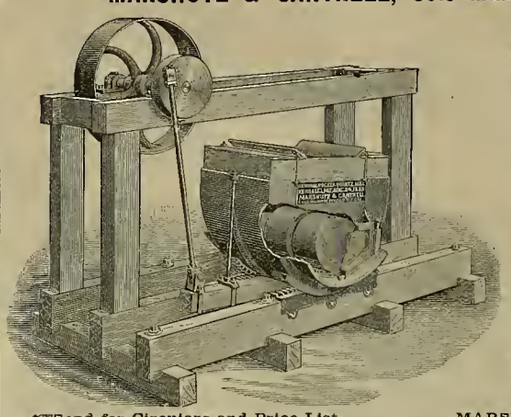
NATIONAL ROCKER QUARTZ MILL.

KENDALL'S PATENT, AUGUST 24, 1886.

CAPACITY, 12 Tons in 24 Hours. 3 H. P.

MARSHUTZ & CANTRELL, Sole Manufacturers.



The Patentee and Manufacturers cordially invite miners to critically examine and pass judgment upon this improved system of milling and amalgamating ores in the following particulars:

1. The cost is less than one-half of stamps of same capacity.
2. The freight to mine is less than one-half of stamps.
3. The cost of erecting is less than one-fourth of stamps.
4. The power to run it is less than one-half of stamps.
5. The wear is less than one-quarter of stamps.
6. There is no wear except on shoes and dies.
7. In point of amalgamation it is superior to any other machine in use.
8. In its simplicity of construction.

We challenge competition with Stamps, Ball Pulverizers or and other ore crushing machines now before the public.

Send for Circulars and Price List. MARSHUTZ & CANTRELL.

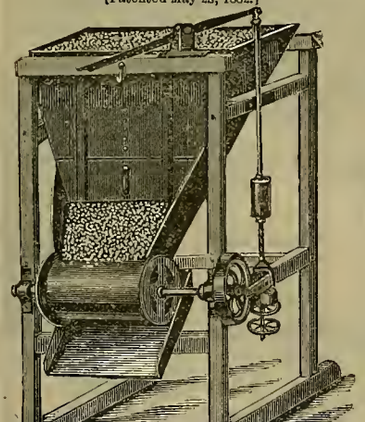
O. S. HALEY, Secretary.

THE ROLLER ORE FEEDER
[Patented May 28, 1882.]



This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.
In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.
Golden State and Miners' Iron Works,
Sole Manufacturers,

Dewey & Co.'s Scientific Press Patent Agency.

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long established, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the Mining and Scientific Press. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, Aug. 7, 1890.

General trade continues to improve. The outlook promises more activity this fall than for several years past.

The money market continues easy with the outlook favorable to a continuance. This opinion is grounded upon the fact that all kinds of farm produce are selling at much better figures than obtained a year ago, while the mines are turning out more bullion. The higher price for silver will also have a favorable influence on the market.

The steamship China, hence July 31st for China, took out the following treasure: Mexican dollars, $16,008; gold coin, $41,601.

MEXICAN DOLLARS—The market is fairly active at 87½@88c, with the Chinese buying.

SILVER—The market fluctuated to lower prices abroad and at the East, but in this city and Carson City, the Mint paid $1.12½. The supply on this coast is light, or, at least, silver is not offering freely. The ore from the mines on the Comstocks is gravitating toward gold, the average now being over one-half gold. Eastern advices continue to report free shipments of silver to Europe where the supply is said to be below legitimate requirements.

QUICKSILVER—Receipts the past week aggregate 301 flasks, and exports 25 flasks to Mexico.

BORAX—Receipts the past week aggregate 1966 cds. The free receipts at this port are due to the cheaper freights by water to New York. The market is steady at current quotations.

LIME—Receipts the past week aggregate 3902 hbls., and exports by sea 100 hbls. to Honolulu. The market is quiet. Concessions, it is said, can be had on large orders.

ANTIMONY—The market is steady. Eastern mail advices report an easier tone.

IRON—Imports the past week aggregate 25 tons of Oregon. The market is firm. Eastern and English advices report a steady, firm tone.

COPPER—The market has an easier tone. English advices, while reporting the market weak, yet state that the undertone is good, owing to the large consumption. The weakness was caused by outside selling. At the East the market is still in favor of the selling interest, although under some speculative and weak holders selling prices are lower.

TIN—The market is dull but steady. European advices are in favor of sellers.

COAL—Imports the past week aggregate as follows: Nanaimo, 4835 tons; Coos Bay, 1100; Departure Bay, 841; Seattle, 1588. Total, 8364 tons. Wallsend for spot is quoted at 50 cts. advance. The market for all kinds is very firm, with the demand increasing. The continued strike at the Wellington colliery is against buyers, although it is said more non-union men are going to work. The tonnage to load at, loading at and on the way from Newcastle, N. S. W., is steadily increasing. The latest advices place the registered tonnage at 49,268.

Eastern Metal Markets.

By Telegraph.

NEW YORK, August 6.—The following are the closing prices the past week:

	Silver in London.	Silver in New York.	Copper.	Lead.	Tin.
Thursday	.50¾	1 1t	$17 00	$4 42½	$20 85
Friday	.51 3-16	1 13¾	17 00	4 42½	20 80
Saturday	.51¼	1 13	17 00	4 45	20 80
Monday	.51¼	1 13	16 85	4 50	20 85
Tuesday	.51¼	1 12¾	17 00	4 45	20 85
Wednesday	.50¾	1 11⅞	16 85	4 45	20 85

NEW YORK, August 5.—The tone of Lake Copper is not quite as strong; nominal rates, 17@17¼c, with sales reported for August at 17c and Arizona at 15½c; casting, 14¾c. The London market is somewhat weak. The Pig Lead trade is moderate and the article freely offered at $4.45.

Mining Share Market.

In the mining share market the Comstocks have been dull the past week under review, with prices gradually settling up to yesterday (Wednesday) in the Middle and North End stocks and also in the Gold Hill stocks, excepting Yellow Jacket and Crown Point. The market acted as if the pool had instructed their brokers not to bid for stocks, but quietly take in all they could. It is just such a market that creates distrust, destroys confidence and causes outside selling. With those in position to know, the opinion prevails that prices are rolling around bottom preparatory to another upward move, although points are out for another break before there is an advance. There is no doubt but that every influence has been brought to bear to have the outside sell, with, to a very considerable extent, success. Leading commission brokers report comparatively few stocks held on a margin by outside dealers. This of itself should inspire confidence in an upward move and attests the correctness of the opinion that an advance is near at hand.

In outside stocks, dealing has been quiet in the Tuscaroras. In the Bodies, reports are current of an assessment soon on Mono, which ought to break the stocks in that group, when there will be a buy. In the Quijotoas, Central developed more strength and activity in the Pacific Stock Board, but Peer, Peerless and Weldon were quiet.

Two assessments levied and more to follow are evidence that the pool is after stock, and that the mining share market is not dead—only sleeping.

From the Comstock mines official letters received from the Gold Hill companies, report lower assays in Crown Point, with the ore giving out. In Belcher the assays were $2 a ton higher. Prospecting work of an important character is going on in Belcher, Seg. Belcher, Challenge, Confidence, Yellow Jacket, Con. Imperial and Alpha. Advices from Savage and Hale and Norcross are of the most flattering character. The development in the former promises better than ever. Our Virginia correspondent writes as follows: In Confidence they are taking out ore through the Yellow Jacket shaft, that assays from $60 to $300 a ton, which they are calling low grade. Reliable miners say Challenge, Confidence and Yellow Jacket are looking better than ever. No one not in the ring can tell what becomes of the ore taken out of the three mines. In Ophir they have gone into an old drift, where they tapped a body of ore found 13 years ago, which they are taking out. The ore assays $80 a ton, although their returns make it only a milling proposition. In Hale and Norcross they are still repairing the shaft. The last ore milled assayed about $17 a ton, and the slimes went $45 a ton—the latter the ring is to get, and the former, after deducting *all* expenses, stockholders will get, if there is any left. In Overman they are hoisting over 100 tons of ore a day. That taken out last week assayed from $90 to $190 a ton, but it is given out as $19 rock. If the superintendent or the management of Overman disputes this statement of the high assays, it can be verified by letting responsible mining men in the mine to examine. He says that there is plenty of high-grade ore, but the ring is getting away with the hoodle.

The Alta management has sent another car of concentrates to Salt Lake. The question arises, who gets the proceeds from the sale of these concentrates?

Subscription rate, $3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

ONE of the Dodge ore pulverizers has been set at work at Juneau, Alaska, and Mr. Archibald Campbell, the owner of the mine, says it works well and crushes more than he expected it would.

Assessment Notices.

GOVER MINING COMPANY Location of principal place of business, San Francisco, California. Location of works, near Pr, town, Amador county, California.

Notice is hereby given that at a meeting of the Board of Directors held on the 14th day of July, 1890, an assessment (No. 2) of twenty-five cents (25c) per share was levied upon the capital stock of the Corporation, payable immediately to the Secretary, at the office of the Company, 13 and 15 Fremont street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on Wednesday, the 20th day of August, 1890, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on SATURDAY, the 6th day of September, 1890, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

GRAY DEW, Secretary

Office, 13 and 15 Fremont St., San Francisco, California

DELINQUENT SALE NOTICE.

CARMELO LAND AND COAL COMPANY, Location of principal place of business, San Francisco, California; location of works, Monterey county, California.

Notice—There are delinquent upon the following described stock, on account of Assessment (No. 1) levied on the Fourth day of June, 1890, the several amounts set opposite the names of the respective shareholders, as follows:

CERTIFICATE OF PARTNERSHIP.

We certify that we constitute a partnership transacting business in the City and County of San Francisco, State of California, and in this State. Its principal place of business is at San Francisco, California. Its name is CONNOR & GRANT. The full names and respective places of residence of all its members are signed hereto, and the said copartnership to commence June 1st, 1890.

SAMUEL B. CONNOR, San Francisco, Cal.
ANDREW S. GRANT, San Francisco, Cal.

STATE OF CALIFORNIA, City and County of San Francisco. } ss.

On this 12th day of July, in the year one thousand eight hundred and ninety, before me, Geo. T. Knox, a Notary Public in and for the City and County of San Francisco, personally appeared Samuel B. Connor, of said City and County and State, and Andrew S. Grant of the same place, each personally known to me to be the persons whose names are subscribed to, and who executed the within instrument, and they acknowledge to me that they executed the same.

In witness whereof, I have hereunto set my hand, and affixed my Official Seal, at my office, in the City and County of San Francisco, the day and year in this certificate first above written.

[NOTARIAL SEAL.] GEO. T. KNOX, Notary Public.

DIVIDEND NOTICE.

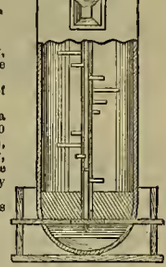
CHROME STEEL WORKS, Brooklyn, N Y.
H. D. MORRIS, Agent,
220 Fremont Street, San Francisco, Cal

Special attention given to the purchase of Mine and Mill Supplies.

COMMON SENSE PULVERIZER AND CONCENTRATOR.

PATENTED DECEMBER 31, 1889.



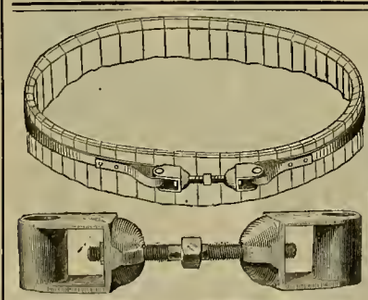
This is the most practical machine yet discovered for working Gravel, Cement, Clay, etc. By its use you avoid crushing the rocks, which are washed clean, while at the same time it pulverizes the cement and clay and saves the gold, though fine as flour.

You do away with a long line of sluice-boxes and only use about six inches of water. One hundred tons or more of gravel can be worked every twenty-four hours.

It consists of an iron cylinder about sixteen feet long, set horizontal, in which a shaft filled with projecting teeth or arms set in spiral form is made to revolve from 150 to 250 revolutions per minute. At the discharge end of the cylinder there is a screen, where the coarse rock is thrown out, while the finer material runs into another cylinder, built in the same way, about twelve feet long, the shaft of which is made to revolve double the speed of the first one, thereby breaking up the finer pieces of cement or clay and freeing the gold, which is deposited in the bottom of the cylinder.

Satisfactory recommendations furnished from practical miners who have seen the machine in actual use. Address

S. K. SNODGRASS,
220 SUTTER STREET, ROOM 13. SAN FRANCISCO, CAL.



BAND COUPLING.
Malleable Iron. All Sizes.

These Couplings are the best in the world, most powerful and cheapest. They have a ball and socket joint, right and left screw and work freely. We use them extensively in our Tank Building Department.

OFFICE ILLUSTRATED PACIFIC STATES, 220 Market St., S. F.

Books on Assaying.

BY C. H. AARON.

PART I.—Gold and Silver Ores.—Price $1

SECOND EDITION.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations well bound in cloth; 1889. Price, $1, postpaid. Sold by DEWEY & Co., Publishers, No. 220 Market street, San Francisco

PARTS II AND III.

Lead, Copper, Tin, Mercury, etc. Price $1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Manipulation, etc.; Lead Ores; Copper Ores; Volumetric Assays; Parkes' Process; Amalgamation; New Process; Preparation of Potassium Xanthate; Electrolytic Determination of Copper in Ores, etc.; Assaying of Tin Ores; Assaying of Mercury Ores; Assaying of Zinc Ores; Assaying of Zinc Ores, New Method; New Assay of Nickel and Cobalt; Assay of Chromium; Assay of Bismuth; Assay of Arsenic; Assay of Antimony; Assay of Sulphur; Assay of Salt; Appendix to Part I; Notes on Crucible Assays; Weighing by Oscillations; Appendix to Part III; The Assay of Lead; The Assay of Copper.

There are 160 12mo. pages with illustrations in the volume which is bound strongly in cloth. Price postpaid, $1.75 Sold by DEWEY & Co. Publishers, No. 220 Market St., S. F

Practical Hydraulics.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers, and Irrigators.

BY P. M. RANDALL.

This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulæ, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are prepared. Thus the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is specially applicable to the Pacific Coast.

Table of Contents.

The following brief abstract of the contents will give an idea of the branches of the subject treated:

General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulæ Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated and Expressed in Formulas and Rules; Flow of Water through Openings; Weir Coefficients; Triangular Weirs; Flow of Water Over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow Through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water Through Short Tubes and Compound Tubes; Flow of Water Through Pipes; Tables of Velocities and Cubic Feet Flows for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend—Circular and Angular; Flow Through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.

Price, $2.00, post-paid. Sold by DEWEY & Co., Publishers, 220 Market St., San Francisco.

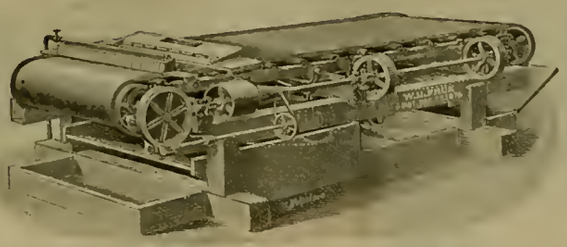
IMPROVED BELT FRUE ORE CONCENTRATOR.

The Best Ore Concentrator in the market, having double the Capacity and doing its work as close as the plain Belt machine, while its concentrations are clean. It is used in a number of Mills, the most notable of which is the Alaska M. & M. Co's Mill, where 24 Improved Belt Frues are taking the Pulp from 120 Stamps, crushing 350 tons per day, and is giving entire satisfaction as against 48 plain Belt Machines, taking the Pulp from the other 120 Stamps.

Price of Improved Belt Frue Vanner, $825, f. o. b.
Price of Plain Belt Frue Vanner, $575, f. o. b.

For Pamphlets, Testimonials and further information apply at office.



Protected by Patents December 22, 1874; September 2, 1879; April 27, 1880; March 22, 1881; February 20, 1883; September 18, 1883; July 24, 1888. Patents applied for.

There are Over 2200 Plain Belt Machines now in Use.

THE MONTANA COMPANY (Limited), LONDON, October 8, 1885.
DEAR SIRS:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Yours truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction that 41 additional Frues and more stamps have been purchased. ADAMS & CARTER.

ADAMS & CARTER, Agents FRUE VANNING MACHINE CO., Room 15, No. 132 Market Street, San Francisco, Cal.

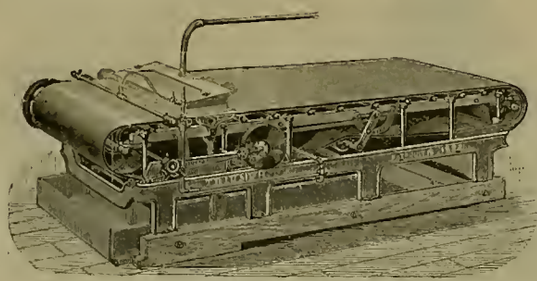
"TRIUMPH" ORE CONCENTRATOR WITH IMPROVED RIFFLED BELT.

(PATENTED.)

The competitive trials which have been held between the "Triumph" Ore Concentrators, the "Frue" Vanners and other forms of concentrating devices, do not warrant the assertion that the "Frue" Vanner is the best ore concentrator in the market. The fact that the "Frues" have improved (corrugated) belts does not militate against the superiority of the "Triumphs;" for, when desired, they (the "Triumphs") can be mounted with a superior belt known as the "Blasdel" Riffled.

Price "Triumph" Concentrators, with Improved (Patented) Belt - - - $650 f. o. b.
Price "Triumph" Concentrators, with Plain Belt - - - - - - - $550 f. o. b.

We are prepared to guarantee the superiority of the "Triumph" over the "Frue" or any other form of Concentrator, for coin if need be. Circulars and testimonial letters furnished on application.



JOSHUA HENDY MACHINE WORKS,
39 to 51 Fremont Street, San Francisco, Cal.

Both the "Triumph" Concentrator and "Blasdel" (riffled) Belt are protected by incontestable letters patent, granted by the Government of the United States.

GRASS VALLEY, NEVADA CO., CAL., Nov. 10, 1885.

Joshua Hendy Machine Works, 39 to 51 Fremont St., S. F., Cal.:

GENTLEMEN—I am pleased to state, in reference to the "Triumph" Ore Concentrators, that four (4) of them were placed in the mill of the Original Empire Mill and Mining Company in April, 1884, and a thorough test made of their practical operation; and their efficiency having been demonstrated, four (4) more were subsequently introduced as the complement of the Twenty (20) Stamp Mill, and the eight (8) have been and are now running with entirely satisfactory results.

At the Ten (10) Stamp Mill of the North Star Mining Company, under my supervision, four (4) are also in successful operation, and from my observation of their practical workings, I am convinced that this form of Concentrators is the equal, if not superior to any other style of Vanners or concentrating devices. DAVID McKAY, JR.,
[Signed] Sup't North Star and Original Empire Mining Co.

N. B. When the stamping capacity of the two above named mills was increased, more "Triumph" Concentrators were purchased, and twenty-eight (28) are now in constant successful operation.

CALIFORNIA WIRE WORKS

—MANUFACTURERS OF—

Steel Wire Rope,

—OF ALL KINDS FOR—

CABLE RAILWAYS,
ROPEWAYS and TRAMWAYS,
Mining, Shipping & General Purposes.

WIRE,

TRANSPORTATION OF ORE BY HALLIDIE'S PATENT WIRE ROPEWAY.

HALLIDIE'S

PATENT WIRE ROPEWAY,

For the Economical and Rapid Transportation of Ore and other material.

Erected by Us During the Past Fourteen Years in Spans of

200 TO 2,000 FEET.

Simple, Economical and Durable.

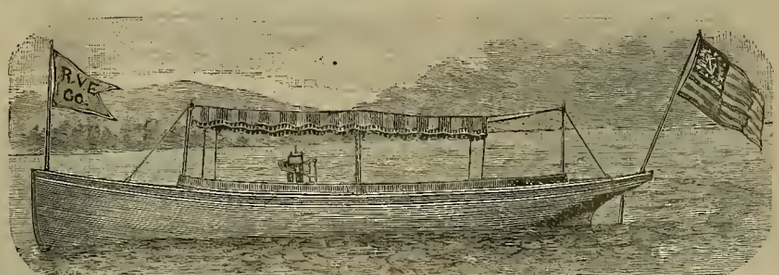
HAVE BEEN THOROUGHLY TESTED In all Parts of the Country.

REGAN VAPOR ENGINE.

NO BOILER! NO FIRE! NO STEAM!
Simple, Compact and Cheap.
No Fire or Flame. Started Instantly without Even a Match.
No Ashes! No Explosion! No Engineer!
FULL POWER OBTAINED IMMEDIATELY.
The Moment Engine Ceases to Run, all Expense Stops.
NO DANGER.
Horizontal, Upright and Marine Vapor Engines and Launches.
Three fourths to Fifteen Horsepower. From $175 to $1200.
Send for Our Large Illustrated Catalogue.

GEORGE HAAS, 324 Market St., Phelan Building,
SAN FRANCISCO, Feb. 21, 1890.

REGAN VAPOR ENGINE CO.—Gentlemen: The 2 H. P. Engine you put up in our factory last November, has given satisfaction beyond my expectations. It does my work better than than those two Electric Motors did, with scarcely any expense for gas. I paid the Motor Company $25 per month for power, while the Vapor Engine has cost me but $2 per month so far. But, be it understood, I have not used the Engine as much as in summer, but the cost of motor would have been all the same, making a saving of $69 in three months. I am satisfied the Engine will pay for itself in less than two years. I use it for freezing cream, run three fans, cocoanut grater, etc.
Yours truly, GEO. HAAS.



Regan Vapor Launches

The uses for small steamboats and launches are innumerable; they are convenient and serviceable for transportation, and are a source of pleasure for those who are fond of sailing. But many have been deterred from purchasing such boats, because of the trouble and inconvenience of using coal, and the necessity of obtaining a Government license, engineer, etc. Our motor does away with these objections. The small space taken up by our engine in the boat gives **more room**; the boat will seat **twice as many** persons as one the same size fitted up with a steam engine. It takes only **two minutes to get under headway**, and can be stopped when running at full speed within the length of the boat, the reverse motion being instantaneous and effective. We carry in stock six regular sizes of hulls, from 18 to 33 feet in length, our models being the best that can be obtained, and built in the strongest and most substantial manner by Thos. Kane & Co, Racine, Wis.

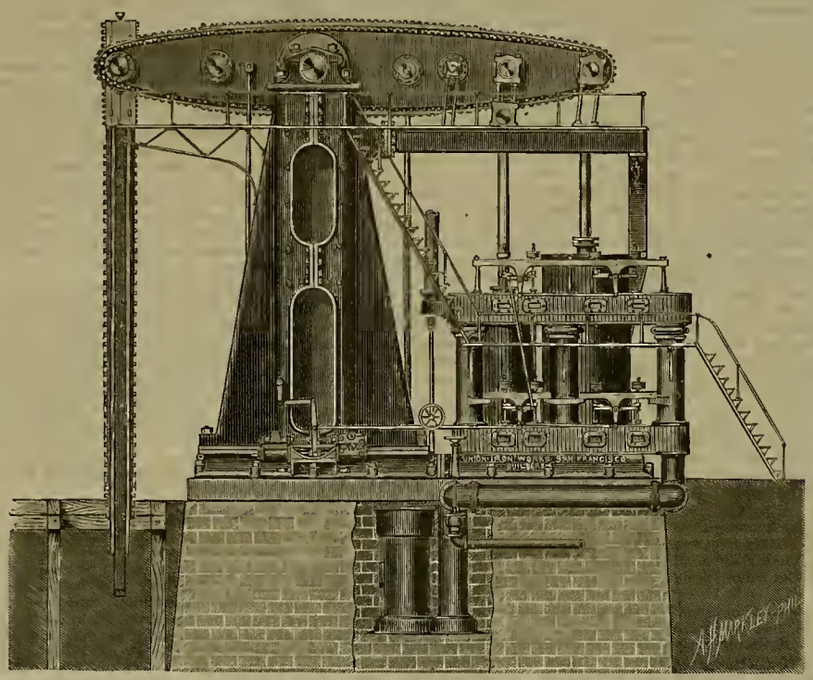
Beam Engines.

On this page is given a true elevation of one of a pair of beam engines designed by the Union Iron Works of this city for the Starr Flour Mills near Port Costa. The engines are of 3000-horse power and the heaviest in the world applied to grinding flour. The mill has a capacity of 7000 barrels a day. The beam engine is the earliest form of arrangement, and must always remain one of the best that can be devised. It attains many important objects that no other arrangement permits. There is but little angular thrust or strain. The beam represents connections of great length. The reciprocating parts are balanced, their weight resting on the trunnion of the beam, so that friction is almost eliminated. The floor space occupied is much less than for directly connected engines. The beam furnishes direct and convenient motion for air, supply and other pumps, which can all be erected within the quadrangle formed by the framing. The first cost is more than for horizontal or directly connected engines; but this is more than compensated by the avoidance of lateral strains and greater endurance, and free working of the engines. When in good working order, the weight of one man on the paddle wheel of a steamboat will turn an engine of 500 h. p. The beam being only part of the transmitting machinery, valves of any kind can be used the same as in the case of horizontal engines. Where the valves have frequently to be operated by hand, or the engines are large, the balanced poppet kind are preferable. The Corliss type are shown in the drawing.



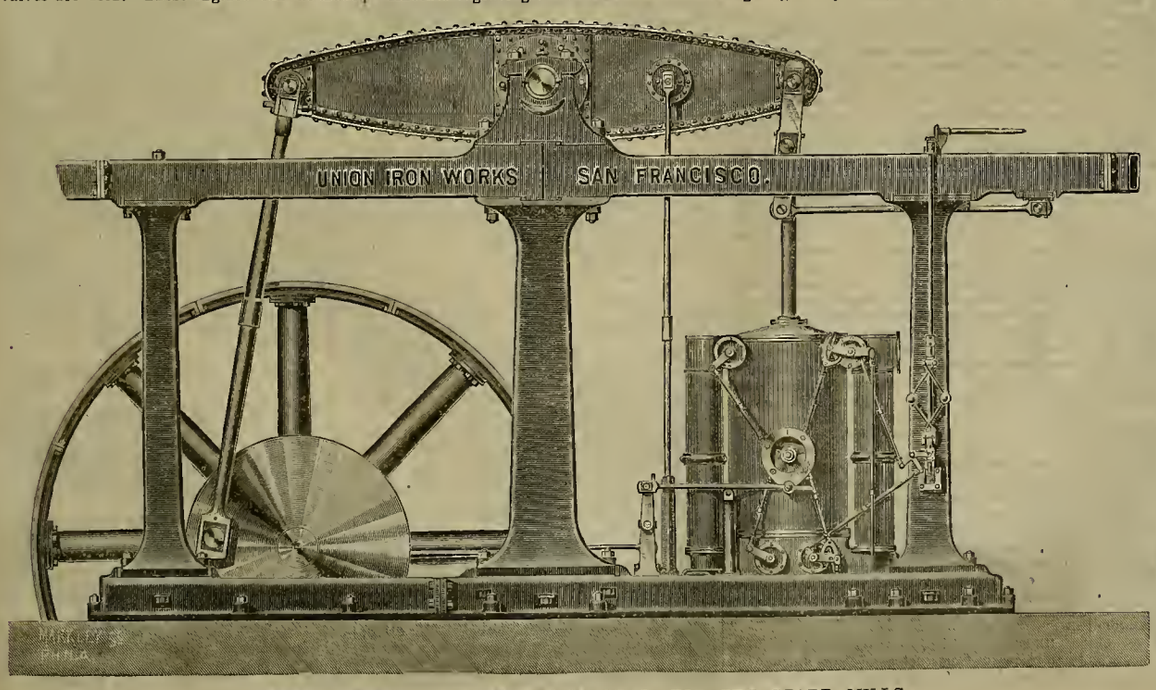
SPECIAL BEAM ENGINE FOR PUMPING PURPOSES.

For inland steamers of the better class, no other engine can compare for endurance, absence of friction, economy of working, and convenience of handling. The machinery is set "on its edge," so to speak, and occupies only a narrow parallelogram fore and aft, leaving the main deck almost clear; in this case poppet valves are used. These engines can be made double or single, or compounded, if required, and arranged to suit any purpose where a large and constant amount of power is required. The Union Iron Works have constructed a large number of beam engines of various sizes and kinds, and are provided with patterns and drawings to suit for all kinds of purposes from 100 to 2000 h. p.

Another engraving shown herewith is an elevation of a differential compound direct-acting beam engine for pumping purposes. The valve motions are controlled by the Davey differential gearing, so the engine automatically adapts itself to the resistance or amount of water, the speed or number of strokes being regulated accordingly. This form of engine constitutes a pumping plant of the highest class, capable of giving a duty of 70,000 to 80,000 gallons by the Cornish rule, and although more expensive at the beginning, is in the end more economical than engines of the non-automatic kind.

The valves are of the balanced poppet class. They are the most durable and easy of adjustment, besides permitting the freest possible inlet and exhaust. The condenser, air and feed pumps are all placed in a pit formed in the supporting masonry and low enough to secure efficient drainage of the cylinders and valve chambers.

On the left is shown the top section of a common pump rod and the mouth of a pump shaft, indicating the manner of making connection. The main beam, as shown, is for a deep lift, the pump stroke being less than that of the initial steam cylinder. This, of course, is varied to suit the hight to which water is raised, or other special conditions. These pumping engines are, when required, made in sections to facilitate transportation in mountainous or other inaccessible countries, all the parts being fitted and numbered at the works so as to be put together with rivets and screw-bolts at the place of erection. In such cases the main column, as well as the beam, is made of wrought iron, and many of the details of steel, to secure strength with light weight. The Union Iron Works make these engines of various sizes to suit special requirements.



BEAM ENGINE, CORLISS VALVE GEAR, FOR THE STARR MILLS.

NEW SILVER BILL.—Senator Teller has introduced a new silver bill in the shape of an amendment to the bill to discontinue the coinage of $3 and $1 gold pieces and 3-cent nickel pieces. The bill differs from the present law in that it retains the continued monthly coinage of 2,000,000 ounces of silver into standard dollars, strikes out the provision that the rate of coinage shall be until July 1, 1891, only, does away with the discretion given the Secretary of the Treasury as to notes issued in place of bullion, either in gold or silver, and provides for the free coinage of silver when the market price of 371.25 grains reaches $1.

DURING the first seven months of the current year, the Ontario mine of Utah produced 554 188 82 ounces of bullion and sold ore amounting to $355,575.21. Seven regular monthly dividends of 50 cents per share were paid, aggregating $3 50 per share, making a total of $525,000 in dividends for the seven months. The total dividends of the company, including No. 170, paid July 31st, are $11,150,000.

THE case of the shareholders of the Nelson Mining Company of Oakland, Cal., to oust S. W. Blasdell from the management of the Nelson mine at Baker, Or., and to have set aside a $50,000 mortgage on the mine, held by Blasdell, has been sent back to the State Court of Baker county by Judge Deady of the United States Court at Portland.

The Gold Belt of Northern California.

Ancient River Channels and Gravel Deposits.

NUMBER X.

[Written for the MINING AND SCIENTIFIC PRESS by JAMES F. TALBOTT, Blue Canyon, Placer Co.]

All of these conditions certainly indicate the correctness of the theory in regard to there being but one main ancient river and tributaries within defined bounds of a certain locality, which contained the original deposit of gold—the source of all recent deposits in that locality. Another fact which tends directly to confirm this view is the discovery within the past decade of a channel deeper than any that has ever been worked or known to exist.

Very Deep Pay Channels.

The effect of this discovery on the future of mining and prospecting will be apparent when it receives the consideration its importance demands. Instead of thousands of dollars being thrown away under the old prevailing ideas that every outside deep gravel deposit overlies an ancient river channel, and the result disappointment and the locality condemned as barren, capital will be intelligently directed, under the new and progressive ideas, toward prospecting for and developing the original source of these deep channels where good and permanent pay will always be found. This deep pay channel was first discovered by accident in the Mountain Gate mine, by a body of cement and top deposit of unknown depth overlying it, which cut off the channel above on which they had been working. The developments made in the deep channel here, indicating its course, induced the belief that it continued down the Forest Hill ridge, and owing to the great width of this ridge between the high rims, the immense depth and width of the overlying deposit, the certainty of a large volume of water and the uncertainty of the position of the channel within this wide scope, it might be on one side of the ridge in one locality and in another on the opposite side. With all of these adverse conditions staring the prospector full in the face, any attempt to discover this channel here required a degree of courage and faith possessed by few, even of this noted fraternity. But one showed up equal to the task, and by his persistent energy Mr. Chappellet has demonstrated to the mining world the continuance of this deep rich channel down the Forest Hill ridge in the Mayflower mine, 15 miles below Damascus.

The success attained by Mr. Chappellet in discovering *the channel* at such a distance below gave confidence in its existence and extent and encouragement in localities above. After an examination of the surface indications, the lava cap inside the high rim-rock, and a correct knowledge of the developments in the Mountain Gate mine, and with all the resources needful to back their confidence, the French company struck the channel rich in the Golden River mine at Red Point, two miles above Damascus. This definitely settles the question in regard to one of the deep original ancient channels in the Middle Fork Divide.

Lava Indicates the River Course.

It is not claimed by this theory that the presence of lava at any given point indicates an underlying ancient river channel; but it is earnestly maintained that a continuous flow of lava for a long distance in a definite course, from half a mile to a mile or more wide, and several hundred feet in depth, within confined bedrock walls, positively indicates approximately the course of the ancient rivers, whose channels are buried hundreds of feet beneath. As branches from the trunk of a fallen tree, lateral spurs may project on either side and form considerable deposits at the junction of some tributary or low depression, but these are off the course of the main flow and are easily distinguished from it.

The Distinguishing Characteristics

Observed in regard to the ancient and modern or secondary deposits are in the ancient deposits a continuous deep channel of a circumscribed width, varying from 300 to 700 feet, within which is found a regular compact stratum of gravel and bowlders on the bedrock, from 1 to 15 feet in depth. The gold is generally fine and the pay uniform in this stratum, which, in the portion of the gold belt here considered, is covered with debris, cement and lava from 500 to 1000 feet in depth.

The surface indications of these deposits are the overlying cement and lava with the bedrock points projecting at right angles from the main ridge.

The modern or secondary deposits, as a rule, are to one side or the other of the main ridges, and are distinguished by their great extent in width and depth in many places. The formation is irregular and composed of all kinds of material found in the surrounding country and deposited in irregular strata of bowlders, gravel, sand and pipeclay to the depth of from 100 to 300 feet, and in the extensive basin-like deposits, are capped with from 50 to 100 feet of fine gravel.

In this class of deposit the gold is very fine and intermixed in certain strata, some of which are 100 feet or more above the bedrock, while some of the intervening strata are entirely barren. It is obvious, then, where the gold is distributed through the deposits in this way that they can only be worked by the hydraulic process. There is another class of the secondary deposits where the channels are narrow and the overlying material not so wide or deep. In this class the gold is generally coarse, and found in crevices and spots. In some localities, strata of gravel are found, high above the bedrock, containing coarse gold.

The Surface Indications

Of this class are: They generally run on a direct course between parallel bedrock points, from where they break off into some modern canyon or river, to where they unite with the main ridge at a considerable angle. The lava frequently extends some distance from the main flow out over these lateral deposits.

To review, the practical points are, the tributaries coming from various directions in the mountain section united somewhere about the upper border of the gold belt and formed the main continuous rivers in the Pliocene period; and by the steep grades in the mountain sections, the greater portion of the gold was carried down into the gold belt, where all of the conditions were favorable for concentrating and retaining it in the original Pliocene channels. The regular deposits in these channels may be compared with the true fissure mineral veins which do not run out or diminish in contents, while the irregular secondary deposits are compared with segregated and pocket veins, which, though often very rich, cannot be relied on as permanent.

The Term "Divide,"

As used here, implies one independent river system of the Pliocene period, disconnected from any other, the same as the present rivers. In comparing the Middle Fork with the North Fork divide, we find a very striking resemblance in general outline and conformation of the country up to a certain point, above which each divide has its own local peculiarities. The Middle Fork divide is separated into two main ridges by a bedrock country through which Shirt Tail canyon runs. The North Fork divide is separated in exactly the same way by Bear river.

About Spring Garden, on the Forest Hill ridge, the gravel deposit runs up under the lava. About 12 miles distant to the northward the same conditions are observed on the Iowa Hill ridge at Iowa Hill. From these distant points, in a continuous course, the two lava capped ridges converge to a certain point above and unite on the main divide, which is not more than a mile in width. A complete parallel to this is found on the North Fork divide, where, at Bogus Point, on the Sheep Run ridge, the gravel crops out from under the lava; and about 20 miles to the northwest, on the Nevada ridge, the extensive gravel deposit at Blue Tent runs up and dips under the lava cap on that ridge. From Bogus Point on the south and Blue Tent on the north, the two lava-capped ridges on a continuous course converge to a certain point above, where at one time they were evidently connected at Bear valley.

All the conditions and developments are so well known on the Middle Fork divide that it is unnecessary to refer to them further in comparison, and as all of the conditions are of the same character throughout the whole western slope of the Sierras, we conclude as is the Middle Fork divide so are all the other lava-capped divides.

In this article I have endeavored to

Outline a Systematic Theory,

By which all of the apparently mixed up and conflicting parts can be made to harmonize and form one comprehensive whole. It is the result of my personal observation and experience as a practical miner for nearly 40 years, and is based on observed facts and natural methods. In regard to the facts, I challenge an examination by any mining expert or scientist. As to the correctness of conclusions, I leave the practical progressive miner to decide.

The extensive, unexplored and unprospected section of country is the ridge extending from Bogus Point to Bear valley. This section occupies a position right on the gold belt, covering nearly its entire width from west to east, with rich drift mines both north and south of it. Here are present all of the favorable surface indications and surrounding characteristics of those lava-capped ridges where rich drift mines have been struck and are now being worked. No mining section in the State possesses anything like the same facilities of access for travel and transportation of supplies, as the C. P. R. R. runs on this ridge nearly its entire length.

(To be Continued.)

DEATH OF GEORGE T. COULTER.—George T. Coulter, a well-known mining operator, died at St. Mary's Hospital, on Tuesday morning, after a long illness. The deceased was born in Baltimore, Md., in 1842, and after coming to this State, engaged in mining pursuits. He soon acquired prominence as an organizer of large enterprises. His last venture was in the Consolidated Esmeralda mine in Aurora, which he succeeded in placing upon the London market.

THE sum of $252,370 was disbursed in wages to employes of Comstock companies during the month of July. Of the total sum, the Con. Cal. and Virginia office paid out $49,236.75.

San Bernardino County.

Its Mineral and Other Resources.

NUMBER VI.

[Written for the PRESS by JAMES H. CROSSMAN.]

Valleys.

Of the 23,476 square miles of territorial possession confined within the boundaries of the San Bernardino county lines, we find lying south and inclusive of the mountain range of that name 6000 square miles, as previously stated, which is subdivided as follows: South of the range, mountainous land unfit for cultivation, 5297 square miles; land susceptible of cultivation, 703 square miles. North of this range, in the so-called desert regions, an area of 17,476 square miles is subdivided as follows: Valley land, 11,651 square miles; mountainous land, uncultivated, 5825 square miles, making a total of of 23 476 square miles.

Of the irrigable valley lands, 256 square miles contain alkaline, saline and borax deposits. Of these there are 216 square miles of alkaline and saline beds, and the balance is made up of borax-fields.

Of that portion designated as valley land, at least two-thirds is irrigable less the saline and alkaline bedded deposits. This leaves 7511 square miles which is irrigable and susceptible of cultivation by utilizing the waters of subterranean channels through the medium of artesian wells and a system of storage reservoirs for irrigation purposes.

It is a well-established fact known to all "desert men" that an inexhaustible supply of pure water can be obtained from most any of the dry lakes by sinking but a short distance from the surface. The salt, borax and soda beds contain incalculable stores of wealth of such extraordinary richness that the product is freighted by wagons long distances to railroad for transportation to a market.

Leaving the Fertile Valley

Of the south for the desert region of the north, we cross the San Bernardino range of mountains through Tejon Pass at an elevation of 2927 feet. Descending its northerly flank, we enter a broad and extensive valley, whose lowest depression is 2670 feet above the sea level. The valley at this point is not only bisected by the California Southern railroad, but the Mojave river crosses it and enters the desert region proper through the gate at Victor. This low depression or trough is known as the

Rabbit Spring Valley.

Victor, Ord, the Lava Bed range and several other unimportant and detached ranges form the northerly bank, while the San Bernardino and San Gabriel ranges bound it on the south. Its longitudinal extent is from Mojave Station on the northwest to the Colorado river on the southeast, reaching the river at points opposite Ehrenburg and La Paz that lies on the east side of the river in the Territory of Arizona (a distance of 230 miles). Its width varies from 20 to 40 miles. This valley is not continuous with a regular grade, though the mean of the gradients between the two terminal points is 11.40 feet to the mile. Mojave is 2750 feet above the sea level, while the Colorado river shows an elevation of 127 feet at the point designated.

Dry Lakes.

In this distance there are many basin-shaped depressions of considerable area, surrounded by a rim rock. These depressions are known as "dry lakes." They have been formed from the effects of volcanic action, the lava flow from extinct craters having dammed and obstructed the river's flow at a period contemporaneous with the volcanic outburst that occurred in this region. At later periods, these and other volcanoes broke out afresh and assisted in filling the beds of these newly-formed lakes. The soil of the valley is wonderfully rich in fertilizing qualities, formed from the wash of the mountain ranges on the south, and the disintegration and decomposition of the eruptive rocks on its northerly bank, a combination of lime, soda and decayed vegetation. There is no portion of the valley where water cannot be obtained by sinking from ten to 100 feet, and there can be no question but what artesian water can be procured at greater depths.

The Formation and History

Of this extensive valley is simple and easily understood. At a period anterior to the previously mentioned volcanic outburst that changed the topographical features of this whole region, the valley or trough between the two ranges formed the bed of a river of considerable magnitude. In fact, this was Amazonian in its proportions, and received its source of supply from the far north, with numerous streams and tributaries flowing from the mountain ranges through which it coursed for hundreds of miles from its source, in a southerly direction, skirting the Sierra Nevadas on the west to a point near the boundary line of Mono and Inyo counties, Fish Spring and the White Mountain range. This point was the focus of violent volcanic activity that occurred at no very remote period in the history of the world. The resultant effects of this display of subterranean volcanic forces are here seen in every direction; extinct volcanic cones of mammoth proportions built up from base to summit of the material of their own production form miniature mountains, and isolated volcanic peaks surrounded by large areas of lava, scoria, volcanic glass, tufa and other eruptive products. The center of this disturbance occurring in and on both sides of the river's bed, destroyed its integrity, filling the valley through which it coursed from summit to summit, forming a dam of immense proportions, which in turn formed large and extensive lakes, of which Walker lake remains in evidence. The line of disturbance extending northerly from this point, produced similar changes and obliterated all traces of what was at one time an extensive river.

From the dam referred to at the head of Owens River valley it flowed on its course uninterruptedly in a southerly direction, bounded by the Sierra Nevadas on the west and the White Mountain range and Inyo on the east. The latter, geologically speaking, is formed of the oldest rocks on that portion of the continent west of the Rockies; thence via Owens lake through that extensive valley known as Salt Wells, where the flow of this ancient river was again interrupted by a cross-range of eruptive rocks which formed the dam that flooded and formed the last-named valley; thence to Mojave Station; from there to the Colorado river, a distance of more than 400 miles from the dam referred to on the boundary line of Inyo and Mono counties. In corroboration of

The Theory of the River Channel

That I have advanced, W. A. Goodyear, Geologist of the State Mining Bureau, was much puzzled to account for the immense quantity of water-worn gravel and bowlders that he saw during his examination of that region. I quote his own words from pages 273-4 of the 8th annual report of the State Mineralogist: "The material consists of sand, pebbles and water-worn bowlders * * many of them large enough to weigh from one to 20 tons each. They are scattered far and wide. * * It is impossible to understand how ice in any shape could have produced a distribution so uniform, * * nor could the water of any lake or sea have spread the debris in such a way."

The problem would have been easily solved if the river theory, accompanied by a local upheaval, had occurred to him.

I have digressed and left the county under discussion, but the subject is an important one. It was necessary that I should attempt to show that such a river as I have described at one time existed. Its bed yet remains and is the recipient of the water of an immense watershed. Though not at date coming to the surface as a living stream, it unquestionably flows through subterranean channels and finds its way to the ocean. From this source, artesian water, under powerful pressure-head and in immense quantities, can be obtained to irrigate the desert lands of this now barren and unproductive valley. The valley from Mojave to the river Colorado is not less than 230 miles long by a mean of 15 miles in width, aggregating 3450 square miles of irrigable, fertile land which would support a large population. No portion of this land has been surveyed or located, unless it is a small strip on the border of the Mojave river, it being Government land, and unless withdrawn under the Irrigation Act, it can be had by the settler for $1.25 per acre. I have more particularly described this valley as a type of a large number that exist in these desert regions, that are similarly situated. To enumerate and describe them all would fill a volume.

I have thus briefly described the lands of this arid region that require artificial appliances for irrigating purposes (storage reservoirs or artesian wells). I will, by way of illustration, show what can be done with similar lands that receive their supply of water from natural sources, viz.: Springs that discharge at the surface.

Pahrump Valley

Is situated on the boundary line between Nevada and California—about one-half of its territory in each. The valley adjoins the Yellow Pine range on the north, to which it lies parallel, coursing northeast and southwest. Its extent is 40 miles in length by 18 in width, comprising an area of 720 square miles.

On Yountz ranch, two springs with a combined flow of 100 inches, miners' measurement, irrigate the ranch, on which there are five acres in fruit, consisting of peaches, apples, apricots and figs, in full bearing, producing large crops of high flavored fruit. There is one acre in blackberries, and there are 2½ acres in vines seven years old, 25 acres in alfalfa (cutting four crops of 1½ tons each season), and 95 acres in barley yielding two tons to the acre. Sweet potatoes are a never-failing crop. Irish potatoes yield from 2 to 2½ tons to the acre.

Wintere Ranch,

Known as the Pahrump, is situated six miles distant, and has 75 acres in barley, 125 in alfalfa, and 20 in fruit of all varieties producing equally as well as the one first described, with never-failing crops. The atmosphere is so dry that grain can be stored and preserved in cribs for several years without deteriorating. This ranch is also supplied with an abundance of spring water for irrigation purposes.

The Death Valley Basin

Is in Inyo and San Bernardino counties—much the larger portion being in the latter. Its area is 180 square miles—60 long by 3 in width.

The surface of this basin is covered by an

earthy, pulverulent, ashy-gray substance containing a large percentage of sode, salt and borax, forming, as a rule, separate and distinct beds. Large areas are covered by an efflorescence of these crystallized minerals of a dazzling whiteness. This, combined with the caustic-heated dust that rises from the bed, affects the eyes of the traveler to that extent that he is compelled to use protective measures while crossing it. The alkaline, saline and borax products of this basin set an important figure in the mineral resources of the county. They will be described more particularly under the head of "mineral districts." The basin is superficially covered by these powerful mineral substances, but in many places on its had fresh and drinkable water can be obtained by sinking from 8 to 20 feet, where a stratum of a hard cemented earth is reached, called "the hard pan," usually from 2 to 3 feet in thickness. Below this, fresh water is found. The basin is said to lie from 100 to 200 feet below the level of the sea, but of this no accurate determination has ever been made. This valley is a type, on a large scale, of many others in this region of smaller dimensions.

Borax Lake

Comprises an area four miles in length by half a mile in width. Its surface is covered by a boracic efflorescence and the water below the surface is highly charged with this mineral, which is being utilized by and belongs to Messrs. Searles Brothers. Their refinery is in the vicinity at the head of the lake, which is situated in township 19 N., range 41 west, M. D. M.

Crystal Salt Valley

Lies 27 miles S. E. of Danby, 4 miles S. E. from the southerly end of Old Woman's mountain and 50 miles from the Colorado river, at an elevation of 600 feet above the level of the sea. It forms a basin-shaped depression of 4 by 10 miles in extent. The central portion is 5200 feet long by 2600 feet wide and is covered by a saline efflorescence. Below this crust are found prismatic crystals of great beauty and transparency which are highly prized by scientific institutions and mineral collectors for cabinets, as they do not deliquesce on exposure to the atmosphere. They occur in a solid bed of crystalline salt of unknown depth and extent. Its product is mined by open cuts and hauled in freight teams for a distance of about 30 miles to Danby, for transportation by rail to a market. Of the many unenumerated valleys of extent and importance in these desert regions, we find Soda Lake, noted for its alkaline and saline product; Chimbneva for its agricultural character, and Bear and Holcomb valleys for their immense gold-bearing ledge.

(To be Continued.)

The Bodie Mines.

The Standard mine at Bodie is taking on a new life under its new superintendent, Arthur Macy, and promises to again be the "old reliable" mine of all this section. He has made a new departure in the working of the valuable ores of that mine by putting in two Frue concentrators to reduce the expense of milling and, at the same time, obtain close results. While the mill, under the new management, has been running only about ten days, it is considered by all interested that the new process in the milling of the Standard ores is a success, although no "cleanup" has yet been made; but Mr. Macy is so well satisfied with it that he has ordered three more concentrators, which will give him five—sufficient to give work for the 20-stamp mill of the company. The success of the Standard under its new management will be an incentive to other companies, notably the Bodie Tunnel, which has also been placed under the management of a thorough miner—Supt. J. R. Ryan, formerly of the Comstock—to inaugurate the same system of reducing their ores and place the Bodie Tunnel on the list of paying mines, as it is well known that it has plenty of ore awaiting a cheap and thorough process of working.

Mono county, which has poured millions of gold into the commercial marts during the past 12 years, has not been half prospected for its mineral wealth, and many prominent mines have been idle for years awaiting a cheap system of ore reduction which will enable them to take on a new lease of life, be productive and a joy to their owners, if Supt. Macy makes a successful "cleanup" of his present workings, and demonstrates the fact that our ores can be worked closely and economically.—*Chronicle Union.*

NEW REDUCTION WORKS.—The erection of a $70,000 gold extraction works has begun at Grass Valley. The main building will be 107x47 feet. The principal factors of the plant will consist of two sets of Krom's 26-inch steel rolls with crushers, two roasting furnaces and six two-ton chlorinators of the Pollok patent, with other necessary machinery. The rolls and crushers will reduce 30 tons of ore per day, and the chlorinators will treat 200 tons per week, on the basis of ten tons daily. Water will be utilized for what power is desired, two water-wheels having been ordered. The works are being erected by the Grass Valley Extraction Co. of Edinburgh, Scotland, and a representative of the company is now superintending operations at Grass Valley. If found necessary, a smelter will be erected later.

Black Sand Mines.

Gold on the Ocean Beach in Santa Cruz Co.

"Would you kindly direct us to the Black Sand gold mines?"

It was in the village of Aptos, on Friday morning of last week. The speaker was M. H. Hyland, and his companion was a representative of the San Jose *Mercury*.

"They're taking out a good deal of gold down there, ain't they?"

"Oh, yes. I am told they've got a good thing," responded the lawyer without cracking a smile; "but could you tell us how to get there?"

"Where do you want to go—to Cope's or to Raymond's?"

"To Raymond's," was the answer, given at a venture, for neither of the gold seekers knew anything of Cope or Raymond, nor the mines, except that they were taking gold from the beach sands somewhere down the coast, not very far from Aptos.

"Want to go to Raymond's, do ye? Well, now, if you could only get down to the beach here, it would be easy enough, but you can't, cause the gate is locked. You might get the key from Slawson, though. No," he added after a minute's reflection. "Ye can't find Slawson; he went up into the mountains this morning. You'll just have to go around by San Andreas."

"How's that?"

"Well, you just go down the road past a white house, and then you turn to the left and go about three miles, and then you turn to the right and go four miles and pass a barn, and thee you go through a gate and across a field and down a big gulch and under a bridge, and pretty soon you'll come to the mine."

"How far is it?" asked Mike with a groan.

"About nine miles that way. If you could get on the beach, it wouldn't be so far."

The gold-seekers were in for it, and while they had but faint hope of following the directions, they were bound to try, and pushed on.

They succeeded more easily than they expected, and after an hour-and-a-half's drive over sandy, hilly roads, they passed a barn, opened a gate, went through some fields, descended an almost impassable gulch and followed its course until it passed underneath a high railroad bridge, and on the beach just beyond, came upon the camp of F. H. Hansmann and F. Raymond.

These gentlemen and two machinists from Santa Cruz were busily engaged in putting in place a small engine and concentrator, but they cheerfully passed long enough to receive and answer the numerous questions of their visitors. Said one of them: "You know that the black sands of the beaches of the Pacific ocean in many places carry considerable gold, but it is so light and fine that in most cases it is impossible to work it profitably by ordinary methods. People have been experimenting with the sands here for the last ten years, but for the most part without any great financial success. One lucky individual, with ordinary sluices and riffles, did take out $22,000 from under that bridge, but he struck a remarkably rich deposit."

"You say that many efforts have been made to mine the less rich sand without profitable results; on what do you base your hope for better success?"

"On the fact that I believe we have at last succeeded in obtaining a concentrator that will save the gold," pointing to a machine standing at a little distance from a ten-horse-power portable engine. "This," he continued, "is the invention of Woods & Garcelon at Santa Cruz. We have experimented with a smaller machine, and are satisfied it will do the work with five men, four horses and two common road scrapers. We expect to work from 80 to 100 tons of sand a day."

"How much gold do you expect a ton of sand to yield?"

"We expect to be able to save an average of from 75 cents to $1 a ton."

"What is the depth and extent of the black or gold bearing sand?"

"Its extent we cannot tell. We know that it is found all the way from here to Aptos wharf. We do not think it extends far under the bluff, though Cope's mine, below here, is more than a mile inland, and the sand is brought up from a shaft. The black sand is from two to three feet below the surface of the gray sand and is a stratum of from three to four feet in depth. It will be easily worked, as we will strip the gray sand off with a common road-scraper and convey the black sand to the concentrator in the same way."

At the request of the visitors, one of the men went to the edge of the bluff, and, after digging a hole two feet deep, took out a shovelful of the sand and washed it (upon the shovel) in a seepage pool on the beach, the result showing a multitude of tiny specks of gold, indicating a wealth at that particular spot far in excess of the 75 cents or $1 a ton spoken of.

The miners expressed a belief that they would have their machinery in operation during the afternoon and invited their visitors to remain and witness the experiment, but the time could not be spared.

Upon the advice of the miners the visitors on their homeward trip followed the beach line as far as New Brighton (a mile this side of Capitola) where the high bluff can again be reached, the return being made with much more comfort and in a third of the time occupied by the outward trip. This is a fact that possible future visitors will do well to remember.

On the Ridge.

River Mining to Boom.

In conversation with Mr. C. H. Mitchell on Thursday, says the Grass Valley *Tidings*, we gleaned a number of interesting observations made by him on his recent trip to the Ridge in behalf of the Mining Department of the Census Bureau.

Mr. Mitchell stated that he was astonished at the extent to which the Yubas have scoured during the winter and spring. At Bridgeport, where last fall a bowlder projected out of the river-bed two or three feet, the scouring process has been so decided that from 12 to 15 feet of the immense rock is now in view. In other places he noted that the bed had scoured out, where the current was strongest, to a corresponding depth, and was credibly informed that opposite Marysville the bed is now a foot and a half higher than it was last fall. There are untold thousands of tons of debris yet to be carried down, so our Marysville friends will be obliged to continue the work of raising and strengthening their levees. This is to be deplored, but it cannot be prevented.

Our observing brother editor was very depressingly impressed with the absolute "deadness" of the once prosperous and numerous towns of the Ridge. This is a direct result of the war on hydraulic mining. There is no question but that there are millions of dollars of gold hidden in the great gravel banks, and hydraulic mining is the only feasible method of getting at the treasure. Some day, and not far distant we believe, a wealthy syndicate will buy up these abandoned claims and construct a great flume from the center of the scene of their operations down through the foothills to the tule lands in Yuba and Sutter counties. Hydraulicking will be resumed full blast, and through this flume the debris will be washed into the tule wastes, strengthening the levees and converting thousands of acres of the tules into fairly good land. Riffles will be placed throughout the length of the flume and annual cleanups of the float gold thus caught made. This source of revenue, as all hydraulic miners will admit, will prove an important one. The valley people are not such fanatics as to oppose a project so obviously beneficial to them directly and *indirectly*.

In all fairness the State should take up the flume project and assist in carrying it out. The laws of the land have ruined thousands of her best citizens in suppressing hydraulicking, and if reparation can be made it certainly should be. Agriculture and horticulture are assisted by the State and the miners should likewise be encouraged. It is conceded that California has experienced a period of comparative depression since Judge Sawyer's anti-debris decrees have been enforced. Could anything else be expected when the gold circulation was by one fell blow diminished so materially! That it would be to the interest of farmer, merchant and miner alike to forward any project looking to the accomplishment of such an end is too plain to be discussed. That the project is feasible is apparent.

The Mining Bureau Museum.

The following are among the recent additions to the State Mining Bureau Museum:

Number of rich specimens of silver ores from Montana, from J. Z. Davis and C. W. Leonard.

Gold quartz from Siskiyou county.

Ouvarovite, Shasta county, H. Williams.

Gold quartz, several specimens from Shasta, Tuolumne and Fresno counties.

Large number of coal, iron, copper and other specimens of economic interest from the Eastern States.

Very fine ancient stone ax, Arizona, John H. Ordway.

Rich silver ore, Sonora, Mexico, E. M. Railton.

Melanterite, Petaluma, Cal., Ben C. Hessletine.

Very fine crystals of magnetite, Lake Champlain, N. Y., John Birkinbine.

Chromic iron (several localities), California, D. M. Miller and others.

Pisolitic limonite on chalcedony; dogtooth spar on conglomerate; smoky quartz crystals, phosphate of lime, epidote, garnets, etc., from W. Q. Mason, Volcano, Amador county.

Building stone, Ione, D. O'Neil.

Native mercury on cinnabar, New Almaden, J. B Randol.

Columbite, Etta tin mine, South Dakota.

ANTIMONY AND GYPSUM.—A correspondent of the *Silver State*, writing from Lovelocks, Nev., says: Antimony is being mined considerable. Mr. Senn, who has mines producing this metal near here, and who worked them some two or three years ago, has returned and with him Mr. Edwards, a representative of a company which will purchase the property upon a favorable report by Mr. Edwards. However, whether the mine be sold or not, it will be worked and the ore either reduced on the ground or shipped to California. Thies & Hutchings have shipped three cars of antimony to San Francisco; that metal being high makes those mines valuable. H. J. Bender is also having antimony hauled for shipment. A San Francisco company is about to purchase the gypsum deposit lying about four miles west of town, and if the purchase is made will commence shipping by the 20th of August, and calculate on handling 600 tons per month, there being mountains of the sulphate in sight.

THE BIG TREES.—Gov. Waterman has received a dispatch from the Secretary of the Interior in which he says: It is not true that the lands you mention are about to be open to survey. The sequoia gigantea has been protected by a very recent decision of this department and orders to reserve all of the ground upon which they are growing, both in Tulare county and in Yosemite, for the latter of which, as you state, a bill is pending in Congress. I have written you this day showing the full correspondence on this subject, which is most positive and energetic in defense of the sequoia gigantea.

The Irrigation Surveys.

It is difficult to learn yet the fate of the irrigation work at the Government expense. So far telegrams seem to indicate the likelihood of the withdrawal of the appropriation for the continuance of the work under the Geological Survey, as both the House and Senate have acted thus far in that direction.

There seems to be a serious conflict in the statements put forth as to the character of the reservation of public lands under the Act of 1888, to which allusion has been previously made in these columns. For example, Senator Dolph of Oregon writes to a Portland paper as follows:

"It has been construed by the Attorney-General and Secretary of the Interior as withdrawing all irrigable lands of all the arid region from the operation of the land laws without any action of the department, and it is held by the department that, as the irrigable lands cannot be segregated from the arable lands without a survey, the operation of the general land laws in all the arid region is suspended, not only as to irrigable lands, but as to arable lands, timber lands, etc.

"This region, as marked out by Major Powell and adopted for the action of the Interior Department, is substantially bounded on the north by the Dominion of Canada; on the south by Mexico; on the east by a line drawn nearly through the middle of North and South Dakota, Nebraska, Kansas and Texas; and on the west through Oregon and Washington by the Cascade mountains; and through the upper part of California by the Sierra Nevada mountains to about the latitude of Santa Cruz, from which point the Pacific ocean is the boundary, being a tract of land containing approximately two-fifths of the area of the United States."

Such a reservation of public lands from settlement naturally would awaken the strongest opposition from representatives of sections which depend largely upon the settlement of adjacent public lands for their development, and suggest the conclusion which they freely make that the Texas representatives relish that because Texas owns all her own unoccupied lands, and to shut up Uncle Sam's real estate office would send customers to the Texas land-dealers. But this conclusion does not seem to be a fair one if the statement attributed to Secretary Noble in the following telegram is the true one:

"An answer to inquiries regarding the irrigation surveys contained in the recent Senate resolution was sent to the Senate to-day by Secretary Noble. He states that the Director of the Geological Survey actually surveyed and marked the boundaries, and that the areas of the sites for reservoirs were by him selected under the Act of 1888, and that the tracts so segregated were so marked that they can be discovered on the ground and delineated on the Land Office maps.

"In the reservoir site selections only so much land has in each instance been reserved as is intended to be used for storage of water. It was not intended, the Secretary says, that the surveys and selections under the Act of 1888 should be carried to the extent of planning a system of canals, ditches, checks and furrows for the distribution of water over farms, as it was deemed that people, when they come to cultivate these lands, can better do this themselves.

"The general purpose and plan of the department, the Secretary says, is to preserve the sources of water supply from the possession or appropriation of individuals or corporations. It is believed, he says, that it will be the duty of his Department, so long as this statute remains, to enforce it, that its fruits, at least in the preservation of the sources and reservoirs of water, may be kept under either national or State governmental control."

This would indicate that only sites suitable for actual use in the storage of water are reserved and they are clearly marked on the land office maps, and that the claim that "two-fifths of the area of the United States" is locked up is not true. Probably a little more time will straighten out these matters.

A MONSTER IRON GIRDER.—One of the two immense 70-ton iron girders which are to span the assembly hall in the McAllister-street wing of the City Hall has arrived, and has been brought to the McAllister-street side of the building. The girder was built by the Keystone Bridge Company of Pittsburg, Penn., and is the largest ever constructed in the United States, so far as known. It is 105 feet long, and is built of wrought steel plates riveted together.

ANOTHER shipment of bullion, valued at $27 927 46, has been made from the Con. Cal. and Virginia mine to the Carson Mint, making total shipments of $119,578 93 to July account.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

ECONOMICAL WORKING.—Amador *Ledger*, Aug. 6: At Herman Tripp's claim on the Mokelumne river, a short distance above Big Bar bridge, the first cleanup of the mill running on ore taken from a new ledge just opened, was made last week, and yielded the satisfactory sum of $1740. The total running expense was $725, or 61 cents per ton for mining, hauling and milling. This we believe breaks the record of economical gold mining. The run amounted to 1200 tons, yielding an average of $1.45 per ton. Such ore is generally looked upon as worthless for practical purposes, but here it is made to yield a profit of over $1000 on the month's run. Tripp says he would not wisb anything better than $2 rock, and plenty of it.

Inyo.

SYLVANIA.—Inyo *Index*, Aug. 6: J. J. Gunn and Arthur Smith returned from inspecting mines and mining prospects at Sylvania last week. Mr. Gunn tells us that there is in that district every indication favorable to the building up of a large and flourishing camp. At present there are about 70 men in the vicinity, and it is probable that this number will soon be largely increased. The Liberal and Climax mines are those which are attracting most attention, the bond having been extended to August 14. There are 700 tons of ore on the Liberal dump. The Great Western, State Line and Hazel Green mines, belonging to Buser & Son, have been worked to a depth of 100 feet. For a new camp the showing made is excellent.

BIG PINE.—Teams went to Saline Valley last Friday to commence to baul out borax once again. Shober & Son will put on two 10-animal teams, Hall Bros. one 8-animal team, and June Smith one 8-animal team. Before fall there will be some more teams put on. We are informed by Conn & Trudo that they are now making about 60 tons of borax per month. Sam Piper and Chris Engle have purchased the 12-foot overshot water-wheel from the Campbell estate and J. Y. Ashmore bauled the same out last Friday to Fish Lake Valley. It will be put up at Piper's mine to run his arastra. May success ever be with them.

PANAMINT.—Cor. Inyo *Index*, Aug. 6: H. G. Chickering has been busy for the last two months on bis Oroville mine and has struck a fine body of high-grade ore, of which be is now taking out considerable quantities. The Wyoming has been leased to Rose, White, Curran & Co., who for a month bave been making extensive preparation for future working. There is a rumor to the effect that capitalists are making arrangements to work the Wild Rose antimony mines upon a large scale. At Panamint a large ledge, called the Anaconda, has lately had some work performed upon it. A shaft of 60 feet in depth has been cleaned out; two tunnels which were covered up by debris, which for years had slid down the mountain-side, completely hiding their existence, have been reopened, exposing several bodies of fine ore; one nearly six feet wide averaging 48.34 ozs.; one from four inches to a foot of 103-oz ore; one 98.70 oz.; one 18 inches of sulphurets assaying from 29 to 65 ozs. Wherever work was done to clean out the old workings, ore was encountered which could be advantageously manipulated. The Anaconda mine can be traced for a long distance. It stands almost perpendicular, lying in a hydro-mica schist formation, the same apparently being the formation underlying the silurian rocks that most of the mines of Panamint district are found in. The Anaconda being in an older formation has every indication of becoming a fine piece of silver-producing property. The ledge is over 20 feet in width and has been very appropriately named, as it is a veritable Anaconda, for innumerable ledges seem to be drawn toward its folds. A short time ago, parties in the interest of an English syndicate were examining mining property in the vicinity of Panamint, Indians at Gold Hill are mining gold, packing the ore three miles and working it in arastras. There is every prospect of the Surprise M. & M. Co. resuming operations before long.

Nevada.

EMPIRE.—Grass Valley *Union*, Aug. 2: Supt. Starr informs us that there is a great improvement in the Empire of late. There is a large and valuable ledge in the bottom, and it gets better as the 19th level is reached. An additional force of men was put to work in the mine yesterday, and now counting tributers and all there are about 130 men employed in the famous old mine.

RICH ORE.—For the past four or five days some very rich ore bas been coming out of the North Star mine from the 17 drift west. The ore that has come out of that drift lately is very valuable and many specimens were brought to the surface that were too rich to be put through the mill. The North Star is looking well.

PASSED THE DIVIDEND.—Yesterday the Idaho M. Co. held its regular monthly meeting at the office of the secretary. It was decided at the meeting not to declare a dividend this month.

THE OMAHA MINE.—Grass Valley *Union*, Aug. 6: Supt. George Mainhart stopped the underground work in the Omaha mine yesterday in order that the shaft migbt be repaired and the landing raised. In the meantime, quartz will come through the shaft of the Lone Jack. There is quartz enough to keep the mill running about two weeks, and it will require about three weeks' time to repair the shaft. No men will he idle on this account. The Omaha is looking well in all its working apartments.

GOLD HILL MINE.—Work is going steadily along at the Gold Hill mine. The shaft has now been cleared to the depth of 140 feet. It was very badly caved, but has been put in first-class repair. Geo. Mainhart, who has charge of affairs there, thinks that they will strike water in about 20 feet farther, then pumping will be commenced.

ST. JOHNS MINE.—*Tidings*, Aug. 6: The water is now out of the St. Johns shaft, and sinking has been commenced by three eight-hour shifts. It is proposed to sink about 50 feet without delay, when the sbaft will be on a level with the deepest old workings. A drift will then be run to connect the two shafts, thus affording good ventilation and a means of escape in event of accident. Then, too, it is known that there is a vein of excellent ore in the bottom of the old shaft. The hoisting and pumping plant is of power sufficient to enable operations to a depth of 500 or 600 feet, and has been very substantially erected. The building and works, in short, constitute a model for other structures and plants, having been designed witb a view to provide maximum conveniences and accommodations. Everything works smoothly, and the job as a whole reflects infinite credit on Messrs. Carr & Son, tbe millwrights and builders.

THE NICHOLS MINE.—Work has been commenced on the Nichols quartz mine, bonded by H. B. Nicbols to the syndicate, represented by Judge Calkins of Chicago, for $50,000. Mr. Nichols has taken a contract to open the drain tunnel, which cuts the shaft at a depth of 50 feet. The tunnel is 900 feet in length and is badly caved. Five men are at work on it. This is the mine in which Nichols took out nearly $20,000 in a few months with one or two men. Grading for hoisting and pumping works will be commenced shortly.

BRUNSWICK MINE.—Supt. Fitzgerald reports that since commencing sinking, the shaft has been put down 22 feet, making a total depth of 282 feet. The ledge in the shaft is from 6 to 18 inches thick and the country rock favorable.

THAT BIG TUNNEL.—*Tidings*, Aug. 5: Francis Burns, who is directing the big tunnel project that is expected to cut the richest ore veins of Nevada and Grass Valley districts at a great depth, is an enthusiast on the future of the mining industry in this locality. The big tunnel company has money enough on band to run for three years to come, in which period royalties from ore veins cut and gold from veins owned by the company and opened up by the tunnel will undoubtedly supply sufficient funds for pushing the work to completion, to accomplisb which it is estimated will require seven years' time. The tunnel, including a 70-foot cut, is now in 250 feet, and compressors and power drills will not be required for several months. At the outset a number of bowlders delayed operations, but now the work is progressing more satisfactorily. The enterprise is now attracting the attention of the prominent mining men of the coast, and if in the course of a year or two expected discoveries are made, there will be no doubt about operations being commenced from this end and the early completion of the work. The company owns 2000 acres of mining ground on the line of the tunnel, including a claim adjacent to the Idaho, on which it is proposed to sink a shaft and from the bottom tunnel to meet the workers from the other end.

RICH ORE AT THE NORTH STAR.—Grass Valley *Union*, Aug. 8: The ore coming out of the stope on the west drift of the No. 17 level of the North Star mine, of which mention was made a few days ago, continues to he of extraordinary richness, the gold being coarse and intermixed with sulphurets of the highest grade. This rich quartz when first struck came in a narrow streak, but subsequently widened until it was 10 inches and ribboned with bands of gold and sulphurets. There has been considerable more ore taken out not so rich in appearance, but yet of a high grade, as evidenced by the fact that 225 ounces of amalgam have been scraped from the plates in eight hours, which would represent a value of about $1000. There has been much rich quartz taken out in the Grass Valley district from time to time, but to our recollection nothing to surpass what is now coming out of the North Star. The location of the rich find is at a point farther west of the shaft than ever before worked. This is very encouraging for a mine that was shut down and dismantled some years ago because it was supposed to have been exhausted of its riches.

Plumas.

ANOTHER MINING ENTERPRISE. — Plumas *National*, Aug. 2: During the past week Messrs. Jas. O'Brien of Smartsville and A. P. White of San Francisco have been in Quincy and vicinity looking at the Plumas Ditch and M. Co.'s property, with a view of making a purchase. The gentlemen returned to the lower country Monday, and we are reliably informed that Mr. R. Thompson of Spanish Ranch leaves for San Francisco next week to settle negotiations with these parties for the sale of the above-mentioned property. This valuable piece of ditch and mining property is situated to the north of Spanisb Ranch, the ditch being over 30 miles in length and the claim for drifting purposes very rich. The estimated value of the old iron in the claim is something over $10,000. When in repair, the ditch water for irrigating purposes alone would yield a handsome revenue. At the close of the purchase it is contemplated to repair the ditch immediately, so as to afford abundance of water to the many miners having valuable claims in the vicinity. The enterprise will create a boom at Spanisb Ranch and Meadow Valley, and as this mining section is exceedingly rich in still undeveloped quartz and drift claims, we note the above with a great degree of satisfaction.

San Diego.

SALES AT JULIAN.—Julian *Sentinel*, Aug. 1: The Richmond mine has in time past turned out some good ore, but, like many others in the camp, has only had the assessment work done on it for several years by J. R. Lowe, the owner. On last Monday it was purchased by Robert Gardner for the sum of $2000. He also purchased a mill-site of W. J. Hastings, whicb is near the property. W. O. Havermale returned to Julian, Tuesday, with the welcome intelligence that the old Helvetia Mining Co. was no more, be having purchased that "troublesome half interest" for $16,000. Mr. Havermale now bas full control of the mine and will push the work of development as fast as money and men can do it. Three shifts were put to work yesterday and the mine will soon he producing ore again. The Fraction and Vulture mines are situated in what is known as the Banner portion of the Julian district, about four miles from the town of Julian. Considerable development work has been done at different times and rich rock has been milled. They join the Cincinnati Belle, wbich was purchased by St. Louis capital some time since, and are also near the Kentuck S. They were purchased Wednesday from Thomas Rowland, the owner, by Waldo S. Waterman and Jerome MacDonald, for the sum of $4000. These gentlemen also own the Cable, in the vicinity of the Fraction and Vulture, and tbey intend running a tunnel across the formation in a distance of 500 feet or more to develop the property. It is expected that this work will commence at once. The names of the owners is sufficient guarantee that it will be done in a first-class manner. The Desert View, Mountain Brow, Julian, Mammoth, City of Richmond, Compromise, Gardner mine (patented) and an accompanying millsite all go at once. The above seven mines constitute what is known as the Blue Hill group of mines, and are located 1½ miles from Julian, and until to-day were the property of Robert Gardner. As we go to press, the papers are being prepared that will transfer the title of the entire group to Gov. R. W. Waterman, tbe owner of the *now* famous Stonewall. This deal means more for the camp than any purchase yet made, the consideration being $50,000. A contract will be let for running a tunnel 1000 feet in length, which will develop this property. Thousands and thousands of dollars have been taken out of the surface of this mountain, and tons of rich ore are now on the dump.

Shasta.

STRUCK IT RICH.—Redding *Free Press*, Aug. 2: Peter Scherer, the original owner of the Eureka tellurium mine, about three miles from Redding, says that recently the company has been clearing out the shaft from which the wonderfully rich tellurium and free gold was taken a few years ago. This shaft was down about 130 feet on an incline, and was last prospected by an expert representing ex-Governor Perkins. After running a short distance and failing to find paying ore, they threw up the hond they had on the mine. But Peter has never become discouraged. He succeeded, with the help of Mrs. L. E. Davis, in organizing a company and for several months has been running a tunnel. Recently they cleaned out the shaft, and upon sinking to a depth of five feet, again found the ledge, some four feet thick and full of free gold. This mine is represented here at the present time by Dr. Isaac Atwood, vice-president of the company, and P. Scherer, treasurer. O. J. Johnson, president, at the present time is in Chicago, This new strike will be good news to those who are stockholders, and is calculated to give the mine a new value in the eyes of the public.

QUARTZ.—Redding *Free Press*, Aug. 4: We learn that Jack Conant bas struck the ledge in the Wheeler mine at Frencb Gulch, and that prospects are bright. Mr. Whitebouse intends to develop the Central mine at Old Diggings, under the management of Mr. Reed, the mining expert. This is good mining property. There were 22 mining men in our city Thursday evening. This shows that our mines are attracting attention in numerous directions. It is reported that the Webb Bros. have made a strike of very rich ore in their new prospect just below the Tom Green mine in the French Gulch district. It is entirely a new discovery. Tom Cummins and a prospector from Frencb Gulch will soon start on a prospecting trip around the base of Lassen Butte. The gold-bearing ore in that region is distinct from any in the State, having a white, soapy, grainless appearance, and the gold occurs in the form of a pink stain. Cummins and bis friend expect to uncover something after the nature of Hayden Hill mine, which is also of a peculiar character and bas yielded somewhere in the neighborhood of $2,000,000. During the past month the Calumet Co. has worked on tests some 300 tons of rock from the company's various mines. The tests have been between the stamp battery with silver plates and concentrators, and the Paul dry amalgamating process, with its accompanying machinery, and arastra working, using the Americanized arastra. We have not been able to get the result of differences, as Mr. Paul declines to give any particulars further than that by the stamp battery you get less than you expect and by the dry way more than you expect.

Sierra.

AT HAPPY HOLLOW.—Oroville *Register*, Aug. 7: J. H. Hogan, who has been in the mountains of Sierra and Butte, says that at Happy Hollow a Scotch Co. were taking out from $20,000 to $28,000 a month. Seventy white men and 40 Chinamen are employed in this mine. A good deal of teaming was carried on, but most of the teams come from Marysville.

GIBSONVILLE.—Cor. *Mt. Messenger*, Aug. 9: All the miners hereabout are at work and the prospect is very promising for a lively mining camp in the near future. Work at the North America drift mine has been temporarily suspended, due to Supt. Schofield being sick in San Francisco. Union Drift Co. are running a prospect tunnel for hack ground, North America Co., Hepsidam, have gravel in their main tunnel 14 feet below the track, making about 74 feet difference in grade of 250 to the old works. Gravel is coarse and appears well on the bottom, but bas not been prospected. Length of the main tunnel about 8000 feet, extending into Plumas county. Mark Schofield has charge of the property during the absence of his brother, Miles, who with Dixon Brabhan of La Porte, own the mine. Average grade of channel from La Porte to the North America drift mine, Hepsidam, is five feet to the hundred, as figured by U. S. Mineral Surveyor C. W. Hendel, who says it is the steepest he has ever had. From Howland Flat to Happy Hollow, grade is three feet by same authority. This is interesting as against four feet to the hundred grade in the Bald Mountain and Extension channel in the Pliocene ridge above Forest City.

Siskiyou.

PINERY DIGGINGS.—Yreka *Journal*, Aug. 6: A gentleman named Deming has recently purchased considerable mining ground at the old Pinery diggings in Scott Valley, and has bonded the Wright & Fletcher and Eastlick mines at Oro Fino, besides investigating the Campbell mine of Quartz Valley and several other valuable mines in Scott Valley and the vicinity, with the same object in view. There is a vast extent of mining property of great value in the entire country from the line of the C. & O. R. R. westward to the valleys of the Pacific seaboard, which only need capital, machinery and labor to develop them to big paying advantage.

Trinity.

NEW RIVER.—Cor. Humboldt *Mail*, Aug. 6: The camp is recovering from the severe winter and those mines being worked are looking well and get better as they go deeper. The Boomer seems to be now in a solid formation and the ore is very rich. The Excelsior has a large lead of good ore in sight, also the Hidden Treasure. The Tough Nut is also furnishing considerable bigh-grade ore. The Uncle Sam looks better than ever and the ore is higher grade. The owners have a new boiler on the way from Eureka, built by Langford Bros. They will probably be crushing within 30 days. Two different parties have a lease on the Sherwood mine, and are taking out some very rich ore. The Ridgeway Co. are about contracting for the completion of the upraise to connect with the old works, where they left very high-grade ore, There is considerable excitement here in regard to the big ledge on Virgin creek known as the Junction, and from present indications it is the biggest thing in the way of quality ever struck in California. The ledge crops out from 50 feet to 300 feet in width and for over 2000 feet in length. Nearly all of it prospects more or less in free gold. I have many $20 prospects. It is pure quartz and highly mineralized. The company, while running a tunnel into this mountain of ore, find a large body that only shows light prospects in free gold, but an assay by Mr. Kustel of San Francisco gives the value of the ore at $113.28 per ton in free gold and sulphurets, I hear good reports from Know Nothing camp, lying just beyond, also from Black Bear.

Tuolumne.

SOLD.—*Independent*, Aug. 9: The Stanislaus gravel mine near Byrns' Ferry was sold last week for $10,000, on a bond of $1000. This mine, the property of Haggin & Hearst, was sold to a Mr. Wheaton, who has already commenced operations. The property, as a gravel mine, is spoken of very highly by mining men, and several parties have of late years bonded the mine, but financial embarrassment overtook them. Mr. Frank McCann negotiated for the sale of the mine for some time, and did succeed, several years ago, in bonding it. The mine was owned by Thos. Evans and sold to Haggin & Hearst for $7000 about 16 years ago. Mr. Evans recently bought the extension.

NEVADA.

Washoe District.

BELCHER.—*Alta*, Aug. 14: The 200 north drift from the west crosscut advanced 13 feet during the week, making its length 192 feet. The face is in a mixture of clay and porphyry and streaks of quartz. The 300 west crosscut from the shaft was extended 15 feet, and is now out 506 feet. The face is in clay, porphyry and low-grade quartz. The 1300 east crosscut is out a total distance of 254 feet. The face is in soft porphyry. The 1300 joint winze is down 67 feet, having been sunk 19 feet, the bottom in low-grade quartz and porphyry. The 1400 south drift is out 80 feet, in porphyry and clay. Have opened the 1000 stope nine sets long by two wide. Will raise the second floor shortly. The 300 stope is up 10 floors from where it was started, and looks well in the top. Shipped to the Vivian mill during the week 274 tons 630 pounds of ore, the average battery assay of which was $22.97.

CROWN POINT.—The 300 east stope is looking and yielding about the same as last week. A considerable amount of rock is still coming from the 300 west stope, and is composed chiefly of old fillings. Shipped to the mill during the week 774 tons 640 pounds of ore, the average battery assay of which was $16.

CHALLENGE CON.—A joint Challenge and Yellow Jacket west crosscut No. 1 from the north lateral drift on the 750 level was commenced and is now in 25 feet, the face showing porphyry. The joint Confidence, Challenge and Imperial west crosscut No. 2, on the 1000 level, is out 333 feet, having been advanced 25 feet during the week, the face showing quartz having no value. The joint Confidence, Challenge and Imperial north lateral drift, on the same level, is in 520 feet, 33 feet having been made, the face in porphyry.

CON. IMPERIAL.—Some necessary repairs have been made to west crosscut No. 3, 500 level, and also to the south lateral drift from top of the raise on the 450 level. The joint Confidence, Challenge and Imperial west crosscut No. 2, 1000 level, is out 333 feet, 25 feet having been made, the face in valueless quartz. The west crosscut No. 1, 1000 level, is out 263 feet, having been advanced 23 feet during the week, the face showing porphyry.

SAVAGE.—On the 300 level, at the end of the north drift, we started west crosscut No. 2, and advanced same 27 feet. On the 1300 level, in the north drift, the place we are cutting out over the winze for a hoisting engine shows a width of 18 feet of good ore. The east drift from the shaft is extended 123 feet. We are extracting ore from the 400, 500, 600, 750 and 1300 levels. During the week we hoisted 551 cars of ore, shipped to Rock Point mill 522½ tons, and milled 455 tons; average battery assay, $20.50. We have bullion on hand and at the mill amounting to $9059.

SEG. BELCHER AND MIDES.—The 1300 joint winze is down 67 feet, having been sunk 19 feet during the week. The bottom is in low-grade quartz and porphyry. The 850 south lateral drift advanced 23 feet since the last report, making its total length 98 feet. The face is in a mixture of clay, porphyry and streaks of quartz.

Eureka District.

ORE SHIPMENTS. — Eureka *Sentinel*, Aug. 9: During the week, the Eureka & Palisade R. R. Co. shipped 240 tons of ore to the Salt Lake smelters. The Lord Byron and Bullwhacker mines of the Ruby Dunderberg Co. are reported to be improving very rapidly and turning out considerable ore. Last Wednesday the Newark Mill Co. shipped by Wells, Fargo & Co. $4000 in silver bullion. The Richmond company is sinking a new shaft on the Williamsburg mine, and will remove the engine formerly used to raise the speiss to the furnace floors to the mine for use at the new shaft.

Hot Creek District.

AT RATTLESNAKE.—Eureka *Sentinel*, Aug. 9: We learn of some very cheering mining reports from Rattlesnake, Hot Creek district, Nye county. R. Gluyas of the New York Co. has a fine mine there, and is taking out a large amount of high-grade ore. Mrs. T. J. Williams also has a good mine, which she is having worked with good results.

Tuscarora District.

NEVADA QUEEN.—*Times-Review*, Aug. 9: Joint upraise from 600-foot level of North Belle Isle carried up 15 feet.

DEL MONTE.—The only work being done is on the second level in line crosscut, where the ore is being opened west and a raise put up east.

GRAND PRIZE.—The extraction of ore bas been temporarily suspended, owing to all the stamps of the concentrator being put on Commonwealth and North Commonwealth ore.

NORTH BELLE ISLE.—Work has been resumed in the old stopes from the 150-foot level. No. 3 upraise from the 600-foot level has been extended

o feet, showing some seams of spar and ore. No. upraise, same level, extended 11 feet. The pay treaks are not looking as well as at last report. oint upraise, same level, extended 15 feet, showing mass of spar and vein. Concentrator running as sual.

YOUNG AMERICA SOUTH.—Stopes producing as sual.

NAVAJO.—The stopes above the 150-foot level ontinue to produce high-grade ore.

BELLE ISLE.—Upraise from the 350-foot level has een extended 16 feet and connected with the 250-oot level. An intermediate crosscut has been run even feet from this raise, cutting a vein showing a ood width of ruby ore. Have resumed drifting outh on the rich ore, 350-foot level.

NORTH COMMONWEALTH.—First level—Stopes re being opened up and all look well. Third evel—Stopes continue about as last reported. Ten tamps of Union mill started on ore yesterday; no assays have been made as yet. Also putting hrough about 40 tons daily at the concentrator; verage assay, $21 per ton.

COMMONWEALTH.—Stopes all continue to yield bout the same grade and quantity as heretofore; 13 cars of ore hoisted, average battery pulp $238 per ton; average assay at the concentrator, $22 per on. Mill is running nicely and everything working veil. Will commence shipping bullion Monday.

ARIZONA.

PROSPECT.—*Silver Belt*, Aug. 4: A rumor of a ig silver strike near Quartzite gained currency this week. Upon inquiry we learned that a man by the name of Morgan, who has been prospecting in that vicinity, located a ledge on the right of the road eading to the Fame mine and about three-quarters of a mile this side of that property. The ledge has been opened for a few feet, and, we are informed, shows a pay streak of horn silver four to six inches n width. It is a good prospect, but more work will be required to determine its value. The Quartet Mining Co. of Globe, Arizona, has been organized for the purpose of mining, milling and developing mines. Milling will be done at the Nugget mill, near Richmond basin. Prospecting has been active n Globe mining district this season. More locations were made in the past six months than in the previous two years.

TODD BASIN.—Mohave *Miner*, Aug. 9: Messrs. Meyers & Pumher, who have a bond on the Mexican mine in Todd Basin, have made a rich strike even for Mohave county. Miners who have visited the mine say that there are two ore-hearing streaks n the ledge. The smallest one is 18 inches in width and assays 250 ounces per ton in gold, and is full of free gold. The largest ore-bearing streak is three feet wide and yields three ounces in gold and 80 ounces in silver per ton. They have the ledge stripped and have a showing of 100 tons of this kind of ore in sight. The boys can show the ore and invite any one who doubts the statement they make in regard to the Mexican mine to come and see it. It is the greatest showing of ore yet made in that section.

TONTO BASIN.—Cor. Prescott *Courier*, Aug. 4: The fact that mines can be developed and made to pay without the aid of much capital is being demonstrated here in Tonto Basin. Wm. Burch and four other men have pooled their mining interests. Their ledges are small, that is, from six inches to two feet in width, free gold, and will work from $15 to $20 per ton. While two of the men work on the mines, the other three are building a ditch from the East Verde, a water-wheel and arastras. They will have everything in running order in about a month, without any more care, worry or privation than the ordinary farmer experiences in planting his crop. The beauty of this thing is that it only has to be done once and the income begins right away, while the ranch man has to wait six months for his returns and repeat the operation yearly. The owners of the Grand Prize mine, on Weber Creek, have a complete mill outfit with steam-hoisting works and pump at the mine. A shaft down 160 feet, 250 feet of levels and an average of 18 inches of ore that will go $80 per ton, besides an air shaft 100 feet in depth in ore all the way, and two other shafts, one 50 feet and the other 20 feet in depth, also in ore that mills $20 per ton; there are five men interested in the mine, all workers. They go to work and take out a lot of ore; when they get enough for a run they start up the mill and the work they do is development work, getting enough ore in that way to pay them well. The result will be that in a few years they will have a well-developed mine, worth plenty of money.

BRITISH COLUMBIA.

FOUR CLAIMS SOLD.—Nelson *Miner*, Aug. 6: Last week a mining deal was made that will result in much good to the Kootenay Lake country—the Hot Springs camp in particular. It was a deal that means mine development for ore, and not for a speculative resale. The buyers—Mr. Boyle and Dr. Campbell—made the purchases for the syndicate who built and own the smelter at Revelstoke. The property purchased was the whole of the No. 1, the whole of the United, two-thirds of the Great Eastern and one-half of the Jesse R. Work will be commenced at once on the No. 1, under the superintendence of John Thompson. The first work will be to run an upraise from the tunnel to connect with the incline to drain the latter, it being full of water. It is said to be the purpose of the smelting company to take out 2000 tons of ore this fall for shipment to Revelstoke; but the shipment will depend on the early completion of the railroad from Nelson to Sproat. J. H. Hope, who has been doing assessment work on the Pacific, says that the claim is looking well and that some rich galena ore has been struck. The Baracoda and Birthday claims have been bonded to M. A. McDougal for $1000. They are located on 49 creek. E. Dempsie of Spokane Falls has put men to work on the Sunrise, a claim believed to be the first eastern extension of Hall's Kootenay Bonanza. At Hendryx's Blue Bell, work is still being prosecuted on the tunnel. Drifts are also being run and preparations made for taking out ore. At Wheeler's Krao the shaft is being enlarged for the steam hoist that will be put in as soon as the wagon-road, now building from Ainsworth, is completed. Messrs. Brickell & Herh of Spokane Falls have organized the Columhia Mining Co. to open up and work the Black Chief, Protection, Eden, Crescent, Coronation and Lakeview claims, all located in Hot Springs district. Mr. Herh is now on the ground. W. Sprague of Tacoma, who recently purchased an interest in the Daddy Gallagher—a claim at Hot Springs, adjacent to Wheeler's Gallagher group—has made a strike on it that promises well, the ore being of good quality. A Hot Springs claim that is attracting attention is Clark & Van Hook's Lady of the Lake. They have tapped the ledge by a tunnel, and the indications of a mine were so good that they will continue on work that will fully develop the property. The stoping of ore at the Skyline is being continued. Men are also engaged in grading a site for a working shaft. The point selected is about 200 feet west of the present incline shaft, and it is expected the ledge will be tapped at a depth of about 350 feet. The Skyline is one of the noted properties in the Hot Springs district.

WORK RECOMMENCED ON THE TOUGHNUT.—Development work, under the foremanship of A. Dodds, was begun this week on the Toughnut. For the present, the work will be confined to sinking the shaft, now down 37 feet and partly filled with surface water.

COLORADO.

THE FRANKLIN.—Aspen *Times*, Aug. 5: The work of repairing the Franklin for the resumptinn of active operations is nearing completion, the plant of machinery has been added to and improved, and when the mine starts up again it will be in shape to clear out the water quickly and to hold any future floods in check. Just when work will be resumed has not been learned, but it is understood it will be very soon. The mine has been closed down since the 9th of May, that being the date when the great flood burst into it.

SADDLE ROCK.—Developments in the Saddle Rock are highly satisfactory. The main drift now shows a two-foot streak of heavy lead ore, and this streak is gradually widening. The ore is low grade, carrying only 20 ounces per ton in silver, but it runs high in lead, averaging from 30 to 40 per cent.

IDAHO.

YREKA DISTRICT. — Wardner *News*, Aug. 2: Among the many good properties in the immediate vicinity of Wardner, the Old Abe lode on the head of Elk Creek has by late developments proved itself a honanza. During the last year a great deal of work has been done on the mine and it has been opened in such a manner that the owners are ready to take out ore and ship it, and so pay for the development work, which they contemplate doing immediately. Two parallel veins run through the property, both running high in silver and lying apart about 125 feet. On the upper vein, which was discovered two years ago, a shaft has been sunk to a depth of 40 feet, showing a well-defined vein from 20 inches to three feet wide, with a pay streak of from 8 to 14 inches of gray copper ore, assays running from 35 to 600 ounces silver to the ton. There is also a drift run to a distance of 68 feet on this vein. On the lower vein, which was discovered in the spring of 1885, a tunnel was projected on the claim adjoining the Old Abe. In it a large ledge of iron was encountered, but at that time the owners did not think it amounted to anything, and not till this spring did they discover that therein lies a veritable honanza. Last spring while running a tunnel to tap the upper vein, the lower vein was encountered at a distance of 190 feet from the mouth of the crosscut tunnel. The ledge here is from seven to eight feet wide, with a pay streak of gray copper ore from two to three feet in width, assays from which have ranged from 35 to 100 ounces silver per ton; the remaining portion of the ledge assaying from 10 to 15 ounces silver and from 3 to 10 per cent lead. These claims lie about one mile east of the Bunker Hill and Sullivan mines and are on the quartzite helt. The owners are Robert Horn, Charles Sinclair, Joseph Rogers, Fred Stevens, Thomas Hanley and J. T. Ingalls.

CUSTER.—The owners of the Custer have nearly completed excavating for the foundation of their 150-ton concentrator. This mill will be run hy water-power, a pressure of 300 feet having been obtained.

NEW MEXICO.

PROFITS.—*Southwest Sentinel*, Aug. 9: Frank Vingo received $1800 on Saturday, the profits of his last carload of Little Fanny mine ore shipped to Denver. The Flagler reduction works here are completed and will go into operation on Shakespeare ore to-morrow. Tbese will be run as custom works, with W. George Waring as manager. About 15 men will be employed.

GROWING RICHER. — The Good Luck mine at Camp Loomis grows more rich and hountiful in production as the miners work their way down. Regular shipments are going forward, yet quite an amount of ore lies sacked at the mine. From all that can be learned from miners and others who have visited the Good Luck, this paper is inclined to regard the property as among the richest and most productive in the precious metals of the honanzas of the West. Besides making a populous locality of Camp Loomis and enriching its locators and owners, Messrs. Brockman & Beall, the Good Luck will he the means of affording the Central, Lone Mountain and Camp Loomis district with a $20,000 stamp-mill to crush their ores, as already local capitalists are figuring on the project with every indication of arriving at a favorable result.

OREGON.

PLACER NOTES.—Jacksonville *Times*, Aug. 4: The Sterling Mining Co. is about ready to commence cleaning up, having had a good supply of water for several months past. Work is still being prosecuted hy the Jacksonville M. & M. Co. on its quartz ledge in Jackson Creek district. J. M. Mansfield, R. Moulton and Geo. R. Strickler are reported to have struck rich pay gravel on Jack's creek, a branch of Jump-off Joe. Eight ounces of dust in 15 days is the showing that Ab Giddings is reported to have made in his mine on Hungry creek a short time since. The season just ending has been a propitious one for most of the miners of Jackson and Josephine counties, who have generally made good cleanups. Jack Curtis is doing well at his claim on Beaver creek, having abundance of water and fine prospects. He made a showing of $22.50 in two and a half days' work recently. Adams & Wyant, who are working the placer mines east of Talent, unearthed what seems to he a superior cinnahar deposit. It is being thoroughly prospected at present. S. C. Stockton and Jas. Hopkins have struck the old channel gravel, rich in coarse gold, at the head of Wolf creek, after two seasons' search, and are correspondingly happy. Ennis & Cameron have finished cleaning out their Galice creek ditch, which was seriously damaged by last winter's storms, and will soon commence preparations for next season. Among Louse creek miners who have done well this seasnn are Messrs. Rowe, Beck, Pelton and Hull, who have taken $1200 out of the old Maury claim in two months' time. Messrs. Litton, Pankey, Barnett and Hallock have all done well.

FROM CRACKER CREEK.—Bedrock *Democrat*, Aug. 4: The *Democrat* reporter met yesterday, Dr. M. Ed. Werner, general manager of the Gold and Silver Extraction M. & M. Co. of Denver, Col., who is now on his way to Denver after a two weeks' stay at Cracker Creek, where he has been engaged with Dr. H. Leippman in making a test of the working of the ores of the Eureka and Excelsior mines. Dr. Werner, while not wishing to go into details at present regarding his operations, was plain and frank enough to tell the reporter that his process for working the ores of the E. & E. mines was a success and a short time longer would only be required to demonstrate the fact conclusively. He returns to Denver fully satisfied with the success attending his experiments and leaves his affairs here in the hands of Dr. Leippman, who will carry out his plans fully. On arriving at Denver Dr. Werner will purchase machinery required in the lixiviation process and forward the same to Cracker Creek at once.

UTAH.

THE HORN SILVER.—Salt Lake *Tribune*, Aug. 6: Hon. P. T. Farnsworth, manager of the Horn Silver mine, is in the city arranging for better facilities for shipping ore. He complains that since the fire at Milford the railroad company has not afforded them facilities for sending out ore. In June the mine shipped 2200 tons of ore, and during the preceding months this year the average was about 1600 tons per month. Not a ton has been shipped in July because of no facilities to do so. At the mine there are 1200 tons sampled ready to ship, and some 300 to 400 tons more ready for sampling, and the mine is in shape to send out from 1500 to 2000 tons per month. The question of concentrating this ore in three to one has been talked of, but if the railroad company will furnish ample facilities for shipping this may not be done for some time, but a concentrator is a thing of the future and may come soon, since in the mine there are many thousand tons of ore which must he concentrated to he of any use whatever. Work is being prosecuted on the 3d down to and including the 10th level. New ground has been opened on these levels extending 200 feet north of the old workings, with lots of ore on all these levels. The company has been annoyed much lately in not getting timbers for the mine as fast as they should. Three cars of timbers shipped from Oregon two months ago have not arrived yet, and these particular timbers are needed badly. A regular force of 100 to 110 men is employed in the Horn Silver mine.

BINGHAM.—Salt Lake *Journal*, Aug. 4: One of the biggest undertakings ever inaugurated in this district is the two-mile tunnel just begun by the Niagara Mine & Milling Co. The tunnel is being driven from a point some two miles above the railroad depot and right in the main canyon, to the Spanish and Miller group of mines, where it will tap three properties at a depth of some 1400 feet, and is expected to show up some of the richest ore to he found in Utah. In fact this region has already shown up mineral that discounts the Ontario away in the shade, running up into thousands of ounces to the ton of pure silver. Why this rich deposit should remain undeveloped is a question that can only he answered by saying, simply a lack of capital, or rather the lack of some one with sufficient hack-bone combined with capital to take hold and develop it as the Ontario has been of late. This is the matter in a nutshell. Bingham has always been considered a low-grade ore camp, and the reason of this was because the surface only was skimmed and nothing has been done to speak of in deep sinking, and there is where the best results always come from.

WASHINGTON.

LEDGES ON RUBY HILL.—Okanogan *Outlook*, Aug. 4: An *Outlook* reporter visited the base of mining operations in the Ruby district this week and was surprised at the rapid progress that is being made in the development of the principal mines on Ruby Hill. Work at present is confined principally to the Arlington, Fourth of July, Antler and First Thought, each of which is being subjected to a thorough and systematic course of development. The methods and machinery used are the best and most approved for the kind of work in which they are employed. At the present rapid rate of progress the developments of the next six months will practically determine the extent and value of the ore bodies of that district. If the result of the work thus far accomplished he taken as a criterion, the outlook is exceedingly hright.

EXCITEMENT AT PORT ANGELES.—Tacoma *Ledger*, Aug. 6: An excited movement, worse yet than the Oklahoma fever of a few weeks since, has struck Port Angeles. This time it is a gold-mining craze. For a long time it has been known that there are very rich deposits of gold and silver ore in the Olympic hills, immediately hack of the town, which have never heen developed. Of late uumerous placer finds have been made in the streams running down from the mountains through the town-site reserve, and experienced prospectors have pronounced it pay dirt. In view of this state of affairs, the arrival of a large mining party from Tacoma on Saturday, which proceeded to stake out and file on large tracts of the Government reserve under the general mining laws, very naturally precipitated a general stampede for mining claims. The land is being taken in mining districts of 20-acre tracts, eight persons clubbing together and taking a quarter-section. In some places a clash is imminent between the miners and farmer squatters, and in the meantime there is much interest and excitement as to the outcome. In many instances truly remarkable finds of color have been made, this fact being vouched for hy many of our best citizens.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING AUGUST 5, 1890.

433,609.—PILE COVERING—Almon Ames, Berkeley, Cal.

433,614.—DEVICE FOR DRAWING BEER—Frank Batter, Marshfield, Ogn.

433,558.—WRENCH—A. T. & A. W. Brann, Dayton, Nev.

433,849.—OIL-CUP—C. L. Burbeck, Ft. Bragg, Cal.

433,670.—ORE-MILL — Carl & Paterson, San Diego, Cal.

433,672.—SASH HOLDER—A. T. Church, East Oakland, Cal.

433,617.—GARMENT SUPPORTER — Gertie D. Cluff, Lodi, Cal.

433,618.—STENCIL AND STENCIL PLATE—G. H. Cunningham, S. F.

433,452.—COVER-HOLDER FOR DINNER-PAILS—John Dorsch, Tacoma, Wash

433,892.—SAFETY GUARD FOR RAILWAYS—H. Ewing, S. F.

433,787.—SLATE SPONGE—Emma C. Hudson, Seattle, Wash.

433,596.—SASH BALANCE—Axel Johnson, Oakland, Cal.

433,600.—SASH-FASTENER — Benj. Marshall, S. F.

433,484.—HAY PRESS—S. H. & C. L. Miller, Stockton, Cal.

433,540.—STREET PAVEMENT—G. W. Parker, S. F.

433,601.—TRAVELING BLOCK — A. Rewrick, S. F.

433,545.—SMOOTHING-IRON—Silberstein & Amos, Los Angeles, Cal.

433,913.—TOOL FOR INSERTING SAW TEETH—R. P. Smith, Marshfield, Ogn.

433,753.—WAGON BRAKE—R. P. Taylor, Gold Hill, Nev.

433,555.—HORSE CONTROLLING DEVICE—Clara Turney, Sausalito, Cal.

433,608.—GANG-PLOW HARROW—W. A. Zumwalt, Farmington, Cal.

The following brief list by telegraph for Aug. 12 will appear more complete on receipt of mail advices:

California—Ciser Bazus, S F., mat for fermentiug vats; Jerome B. Harris, assignor of one-half to J. Gambetti, Stockton, traction machine; William P. Humpbreys, assignor by mesne assignments to A. M Stinson, S. F., joint connection for suction pipes and protectors of dredgers; Charles A. Hussey, Fort Bidwell, cartridge shell reloader; John Isele, San Diego, spring motor; Angus E. McMillan, Oakland, miter box; Edward E. Park, S. F., rotary blotter.

Oregon — Charles Hill, Portland, clothes-book; William A. Miller, Wapintia, crosscut saw; Martin L. Pipes and E. F. Pernot, Corvallis, copy-holder for type-writing machines; Junius F. Whiting, Albany, means for reaper and mower knives.

Arizona—Dudley I. Craig, Silver King, adding machine.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

SASH BALANCE.—Axel Johuson, Oakland, assignor to the Marshall Improved Window-Furniture Co. of S. F. No. 433,596. Dated Aug. 5, 1890. This invention relates to sash balances and that class of springs therein used known as spiral, and it consists in a spiral spring returned upon itself so as to form independent layers the one within the other. The general object of the invention is to provide for the maximum strength or tension with the minimum length of spring and to better equalize the power of the spring. The spring is especially intended to be applied to the form of sash balance patented by Benjamin Marshall, Jan. 23, 1890.

TRAVELING BLOCK.—Assaria Rewrick, S. F. No. 433,601. Dated Aug. 5, 1890. This invention relates to that class of traveling blocks for the main sheet of vessels, and it consists in the novel construction and arrangement of the block. The object of the invention is to provide a simple and effective device of this character which will readily move from side to side, and is so constructed that it will permit the sheet to pass over from one position or direction to the other without interference.

PILE COVERING.—Almon Ames, Berkeley, assignor to Robt. J. Davis of S. F. No. 433,609. Dated Aug. 5, 1890. This patent covers certain improvements for protecting piles against the ravages of marine insects and worms. The pile covering consists of sheets of metal wrapped around the pile and having their meeting edges united so as to form a single longitudinal joint, with bands or rings which fit over the adjacent meeting ends of said sections and joints.

DRAWING BEER.—Frank Batter, Marshfield, Oregon, assignor of one-half to Lars Clemmensen. No. 433,614. Dated Aug. 5, 1890. In drawing beer or other liquids from casks in which it is contained under considerable pressure, it is necessary to draw the beer very slowly to prevent too great a quantity of foam, and in order to overcome this objection, the gas is frequently partly discharged from the cask so that when the beer has nearly been all drawn it becomes flat. This invention consists of an attachment to an ordinary beer-faucet whereby the beer can be drawn with greater rapidity without the necessity of reducing the gas pressure within the cask,

MECHANICAL PROGRESS

Alloys of Steel and Nickel — Mitis Metal.

The ever-increasing demand of the world at large for greater rapidity of locomotion on land aod sea, greater economy of fuel and great motive power in small hulk, has created the necessity for the production of improved materials of constrnction which engineers can nse with confidence and snccess. Much sustained effort has accordingly heen devoted hy onr metal manufactnrers and metallurgists to the examination of the properties of new metals—new, we mean, from a commercial standpoint—and aleo new alloys or old alloys stndied under improved conditions. The many new materials now available for engineering purposes are the results of this work, and it is interesting to note how varied are the properties and capahilities of the newer commeroial alloys.

Mr. Nordenfelt's so-called "mitis" metal is intended to meet the demand for wrought-iron castings, or rather castings which have the properties of wrought-iron and yet the free fluidity of cast iron, and it consists of an alloy of iron and alominium which has most remarkahle properties. It· oasts readily, produces sonud castings, which are soft and malleahle, and have great tensile strength, without requiring to undergo the tedions process common to ordinary malleahle iron castings. Mr. Hadfield's manganese steel also possesses remarkahle properties, and alloys of steel with chromium, copper and other snbstances are now, perhaps, not in common nse, hut still they are largely used for various purposes. Aluminium itself, although mostly used as an alloy with copper, yet hids fair, if Sir Henry Roscoe is correct, to come into use as a constructive engineering material. At present its cost forhids this, hut no douht, if the manufacturing difficulty could he overcome, the valuahle properties of this metal would he gladly utilized hy engineers. According to Sir Henry Roscoe, its hreaking strain varies from 12 to 14 tons per square inch, and its specifio gravity cast ie 2 58, and rolled and hammered 2.68—that is, an equal hnlk of iron is rather more than 2½ times as heavy.

This considerahle tensile strength, taken in conjanction with its power of resisting corrosion from air or water, would make its use widely extended if it could he sold at a reasonahle price. However, if we may judge from a paper read hefore the Iron and Steel Institnte, just published in their journal, steei and its modiiications have not hy any means attained their foll and complete development. Mr. James Riley, whose nsme is so well known as an authority on all matters pertaining to steel manufacture, and who has had so large a share in the introduction of mild steei for construction and engineering pnrposes generally, has made a considerahle number of experiments upon the influence of nickel upon the properties of steel. These experiments he descrihes in his interesting paper. Taking a sample of mild steel for example, containing ahout 0 22 per cent of carhon, when annealed the elastic limit would he reached with a tensile strain of 16 tons per square inch, and the hreaking strain wonld he 30 tons per sqnare inch. The extension of a test piece of eight inches in length would he ahout 23 per cent, and the contraction of area ahont 40 per oent. Now, the same composition of steel, to which has heen added nickel to he present to the extent of ahout 4.7 per ceot, at once gives a material standing a strain of 28 tons per square inch hefore reaching the elastic limit, and having, moreover, a hreaking strain of 40 6 tons per square inch withoot impairing the elongation or contraction of area of the specimen to any marked extent. The elongation of an 8-inch test piece is 20 per cent, and the contraction of area ahout 44 8 per cent after rolling and annealing, as with the mild steel sample. With three per cent of nickel and 0 35 per cent of carhon, the elastic limit is the same, 28 tons per eqnare inch, hut the hreaking etrain ie increased to 48.5 tons per square inch. At the same time the extensihility and contraction of area are somewhat reduced.

Steels containing nickel up to five per cent can he machined with moderate ease; heyond that, they are more difficult to machine and the alloys poorer in nickel stand punching remarkahly well.—*Western Machinist.*

AN ELECTRICAL ENGRAVING MACHINE.—Among the electrical inventions recently patented is an engraving machine which is electrically controlled and operated. This little machine appears somethiog like a planer, and like that machine, has a sliding-hed on which the work is placed directly nnder the engraving tool, which is held in a crane neck. The hed has a reciprocal motion under the engraving tool, and is operated hy a level, which, in reciprocating the hed for the work, also reciprocates a carrier upon which the copy is placed. Suspended over the carrier is a very delicate tracing point; this acts as a contact, and is insulated from the supportioo mechanism; the carriage reciprocating moves under this tracing point, which tooches the prejsoting surfaces of the metallic oopy, which makes and hreaks the circuit; at the same time the tracing point is antomatically moved hack at right angles to the direotion in which the copy carriage moves, so that with each reciprooation of the carriage, the oontact point moves over a different part of the original copy. The engraving tool is carried in a frame whloh moves back at right angles to the direction the hed moves in, keeping pace with the rear work movement of the tracing point, and as the circuit is opened and closed hy the action of the tracing-needle, the tool is controlled hy the action of a magnet in the oircuit. This machine, hy suitahle attaohments, will engrave equally as well on a concave or convex snrface as on a level surface, and in the latter may he in a straight line, in a oirole or in irregular curves. To show the valne of this machine, we will suppose that a silver tea service is purchased as a wedding present, and the purchaser reqnests that a monogram be engraved on each article—the engraver can sit down and on one piece engrave the desired monogram, plaoing this copy under the tracing-needle, and starting the machine he may reproduce the monogram exactly like the orighal on each of the articles, no matter if there he a hundred.—*Electrical Review.*

THE MANNESMANN PROCESS.—One of the strangest and at the same time important improvements of onr time is reported from Germany for producing metal tnhes from solids hy the action of "skew rolls." We have already noticed this invention at considerahle length, and again refer to it to state that there are now founded in Germany five factories for this proocss, from which we may infer it has passed heyond the experimental stage. Not only are pipes made in this way, hut also gun-harrels and hollow shafts and axles. Recently a steel tuhe of three-inch hore, one-fourth inch thick and 70 feet long was made, and the molecular condition of the metal is such that its tensile strength is increased hy the process. The following quotation from a foreign journal will serve to give some idea of the process: "Tne har, in its passage through the rolls, is twisted as a thread is twisted in a spinning machine. As, however, it cannot he fed from the ontside as is the thread, and as has heen said, the diameter cannot he reduced on account of the sotion of the rolls, it is forced to draw on the interior for a supply of material." The invention was many years heing developed, and is called the "Mannesmann Process," from the name of the inventor.

CAN IRON BE TEMPERED?—It has heen the general opinion always, we helieve, among hlacksmiths, that iron could not he tempered. Mr. E. K. Wehry of Lost Nation, Iowa, claims that it can he tempered, and he has sent us a piece of a horseshoe which goes to prove the trnth of his assertion. He says in a letter to us on the snbject: "You will see that I claim iron can he tempered or hardened so that a new file oannot touch it. To prove what I claim, I send yon hy to-day's mail a sample of a heel of an old horseshoe tempered in the same manner that I temper all the new shoes that I set. You will see that at last a way has heen discovered to harden iron soccessfnlly. Although thousands of hlacksmiths will tell yon that it cannot he tempered or hardened, I am willing to put up $50 that I oan temper any kind of iron with fire and water alone, no drugs of any kind to he used." This opens up a very interesting question for the consideration of our readers, and we should like to have a general expression of opioion from them on the novel snbject of tempering iron.—*Western Machinist.*

A RECENT MECHANICAL NOVELTY consists of a combination mold and ladle for casting soft metal hammers, thus insuring a snpply constantly at a small outlay, the device in qoestion enahling the old heads, with the addition of a little extra metal, to he remelted, and shapely, serviceable hammers to take the place of the old and hattered ones; nor can the heads of these hammers he jarred off, as the metal closely surronnds the tree-shaped core of the handle, which may be made of common iron pipe, or a rod with pin through the end. The operation is to place the handle in the mold, fasten with the two ringe, melt the metal sufficiently to flow, and then hy depressing the handle allow the metal to flow into the mold. The ladle heing connected and opening directly into the mold, hnt very little heat is required to cast the hammere—that is, just enough to make the metal run. Ordinarily, to secure a good casting, molde require to he heated, hut with this arrangement it is simply necessary to heat the mold simultaneonsly with the melting of the metal.

HANDWRITING ON IRON CASTINGS.—This is accomplished hy the nse of an ink which leaves a snhstantial and hard hody—one that will not he destroyed hy molten iron. The discovery was made hy a Boston man. The writing is done upon ordinary paper and hackward, from right to left instead of from left to right. The paper is then placed in the mold and the melted iron poored over it. The paper is hurned away, hut the ink resists the action of the molten iron and leaves an indented impression upon it.

THE CLOTHES WRINGER FOR THE LETTER PRESS.—They use a clothes wringer for a letter press in one of the largest of the Wall street telegraph offices in New York. The messages to he copied are treated as nsnal until the time for the putting of them into the press; then, instead of the ordinary screw press, whioh it takes time and muscle to use, the message and damp tissne paper are simply run through a clothes wringer.

SCIENTIFIC PROGRESS.

A Liquid Volatile Nickel Compound.

Nickel seems destined to startle the modern chemical world. From being a comparative rarity, except on plated goods, it hcame a common laboratory material hnt a little while ago; then its title to he considered an element was impngned, and now it is hoth triumphantly reinstated and its vapor density, for the first time, determined. These results have followed from the researohes of Mr. Mond and Drs. Qainoke and Langer, which were recently made the subject of a paper read hefore the London Chemical Society. The investigation owed its origin to the need for removing carhonic oxide from producer gas, in order to nse it in the gas hattery described in Mr. Mond's presidential address at the annual meeting of the Society of Chemical Industry last year—nickel aod cohalt heing found to effect this object.

Working in this direction, it has been fonnd that a direct compound of nickel and carhonic oxide, viz., $N(CO)_4$, exists, the new snbstance heing a *colorless liquid*, volatile at ordinary temperatures, hoiling at 43° C., having a specific gravity of 1.3185 at 17° C., soluble in alcohol, henzine and chloroform, and not acted upon hy dilnte acids and alkalies. Its vapor explodes when heated to 60° C. Its vapor density, determined hy Victor Meyer's method, is 6.01, instead of the theoretical value, 5.9; from this, the atomic weight of nickel is fonnd to he 58. The metal itself can he ohtained from it in the form of hrilliant metallic mirrors of such purity as to form a splendid raw material for the redetermination of the atomic weight. The mean valne ohtained hy reducing nickel oxide from this source hy heating in a stream of electrolytic hydrogen was 58 61, correspondieg closely with that previously accepted, viz., 58 52. This proves conclusively that Kruss and Schmidt's assertion that the metal hitherto oonsidered to he pnre nickel is oontaminated with another element, and that all data concerning it conseqoently need revision, cannot he sustained, and replaces nickel as we have always known it among the elements.

The constitntion of the compound $N(CO)_4$ is still the snbject of the keenest speculation. Mr. Mond declined to he "drawn" on this point, admitting the temptation to represent it hy some fascinating ring formula, hut contenting himself at present with a statement of the facts. In connection with this curious hody it is to he noted that no similar cohalt oompound can he ohtained, thus establishing another method of differentiation and separation hetween it and its twin hrother nickel.—*Ex.*

Food Artificially Produced.

No hranch of science presents a wider field for discovery or specnlation than chemistry, especially in that hranch which treats of organic compounds. The discovery of means wherehy many organic snhstances have already heen produced artificially from inorganic sources, has given encouragement to the hope that this mode of prodnction may in the near futnre he made to solve the problem of a futnre inexhanstihle source of hnman sustenance when there shall not he fields enough on the earth to provide its inhahitants with the ordinary food with which they now sustain life.

A German scientist of no less eminent anthority than Victor Meyer has recently made a pnhlic address in which he announced that "we may reasonahly hope that chemistry will teach ns to make the fiher of wood a sonrce of human food."

In allnsion to this expression, *Kuhlow* remarks as follows: "What an enormous stock of food, then, will he fonnd, if this hecomes possihle, in the wood of our forests, or even in grass or straw. The fiher of wood consists essentially of cellnlin. Can this he made to change into starch? Starch has exactly the same percentage in composition, hut, as every one knows, it differs very much in its properties, and the nature of its molecule is prohahly much more complex. Cellulin is of little or no dietetic valne, and it is not altered, like starch, in hoiling water. It readily gives glncose when treated with snlphuric acid, as is easily shown when cotton wool, which is practically poor cellulin, is merely immersed in it. Starch gives the same prodnct when hoiled with weak acid."

To the ahove may he added a quotation from the researches of Hellreigel, which go to show heyond dispute that certain plants transform atmospheric nitrogen into alhomen, and that this process can he improved hy suitable treatment. The prodnction, therefore, of starch from cellulin, together with the enforced increase of alhumen in plants, would, he adds, in reality signify the abolition of the hread question.

It must he horne in mind, however, that theory, fascinating and promising though it may he, is not always capahle of heing followed up hy a practical result.

WHEN WINTER WILL BE SUMMER.—The plane of the earth's orhit crosses the equator at an angle of 23½ degrees, hut it is held that through the attractive force of the sun and moon, or from some other and nnknown canse, the pole is heing oonstantly tilted away from the sun, while the equator is as constantly being drawn toward it. As a consequence, the sun crosses the equator each year a little farther west than the point at which it crossed the last previous year. It is generally helieved that at a remote period of time, say some 20,000 years ago, the place of crossing preceded or went forward to meet the sun, in whioh oase we shonld nse the phrase "precession of the equinoxes," instead of "recession of the equinoxes" as now. This "recession" is ahont 50 seconds of a degree each year, and in consequenoe thereof the time will come, perhaps in some 20,000 years from now, that the sun will cross the equator on the 21st of January instead of the 21st of June as now. When that time arrives the time of the seasons in the calendar will he reversed from what they now are and the Fourth of July will he celehrated in midwinter instead of midsummer.

THE DISTINCTION BETWEEN LABOR AND WORK. Dr. Edward Everett Hale well expresses a fine thought in wishing to revive the old distinction made in the nse of the words lahor and work. Labor refers to toil with the hody or hands. Work implies the skill wherehy mind enahles the hand to do much more than it otherwise wonld. Thns it is said of those who have lived wisely that "they rest from their lahors and their works do follow them." Dr. Hale says God works, hut He does not lahor. The effect of all modern civilization is to make steam and other natnral powers do the "lahor" while man does the "work." This is a distinction less known in Enrope, where a much larger proportion of lahor is nnskilled than it is here. In Massachnsetts it is fonnd that 89 per cent of workers are skilled laborers, while only 11 per cent are nnskilled. Probably the real proportion of unskilled lahor is less than this. In farming, for example, the necessity of skill to effective work is recognized hy all who are acqnainted with this husiness. Yet in the statistics of a census-taker, many skilled farm-workers wonld be set down as unskilled. This prejudice is a serious injnry to the farmer's husiness. The idea that hrain is less needful here than elsewhere, and that physical hrawn is everything, ought to he got rid of. It is injurious and hesides it is not trne.

THE OCEAN UNDERTOW.—The pnhlio has recently heen treated to several sensational articles on "hair-hreadth" escapes from hreakers at pnhlic hathing-places. The dreadful nndertow, which makes such places so dangerous, is very clearly and simply described hy Daffield Oshorne: As each wave rolls in and hreaks upon the heach, its volume of water flows hack again, and as the sncceeding wave hresks over it, it naturally forms an undercnrrent flowing outward, of strength proportionate to the hody of water it contains, and also proportionate in a great measure to the depth of the interval hetween the waves. Where this latter is considerahle, it is ohvious that the water of receding waves will flow with similar effect to that of water going over a fall, and that a person standieg near is likely to he drawn over with it, and thus, if the interval is deep enough, oarried out of his depth.

DEATH FROM ELECTRICITY.—The execution of Kemmler hy electricity has drawn out much discussion and speculation in regard to the precise action of electricity in destroying animal life. A prominent electrician says that just what takes place in the human organism to produce death from an electric current seems to he an nnsolved problem. One of the theories sometimes advanced concerning it is that when a heing suffers death from electric shock, it is a pore oase of internal rupture or explosion from the generation of gas or vapor. In snpport of this view, the way in which telegraph poles are sometimes torn to pieces is referred to. The lightning followe the moist portion of the pole, which is the core or heart; in this oase the moisture is vaporized and an explosion occurs. The high resistance produces heat, the heat in turn steam, and the steam explosion.

ICEBERGS ON THE ATLANTIC are reported to present a much higher altitude than usual the present season. Some have been reported fully 700 feet high. Their mase must have heen in proportion—only one-ninth of it would appear above water. It is thonght that many icehergs in arctic seas, that have remained immovable for ages, have broken loose this season, an event which may forehode great and possihly permanent improvement in Northern temperatures, which may he a heginning of changes in climate that will possihly render the northern portion of this continent more fitted for human hahitation than it has been in the recent past.

A BASIS FOR DURABLE LABEL INK.—It has long heen known that a solntion of hichlorate of eodium, or horax, possesses the property of dissolving or softening various resins which are unaffected hy plain water and hy the great majority of saline solutions. As a hasis for a permanent lahel ink, unaffected hy water or moderately strong acids, there is nothing equal to a half-satnrated solntion of ordinary horax, duly charged with as much orange shellac as it will take np on hoiling for 20 minntes.

A FIRE DAMP INDICATOR.—A small instrument has heen devised for use in mines to indicate the presence of fire-damp, or in gas mains to indicate the presence of gas. The invention is hased upon the property certain metals have of evolving heat in the presence of hydrogen gas.

GOOD HEALTH.

Influenza and Faith Cure.

The impression seems to be gaining ground that faith cure and mind cure and all the cognate cures are much more effective when there is nothing the matter with one than when the body is really ill or diseased. An illustration of this recently occurred in Jersey City, where a well-known citizen had been an ardent believer in and advocate of the faith cure. He had gone so far as to build a chapel and dedicate it to the cause, and had impressed the wonders of faith cure upon his family; but one day the influenza came along, and as it entered the door the faith cure flew out of the window. The "grippe" was too much for faith, and the doctors had to be summoned.

No one will attempt to deny the influence of the mind over the body in many cases, nor the reflex influence of faith or prayer or any other outward demonstration. There are certain maladies of the body which may be reached more readily and effectually through the mind than in any other way, but from this it does not follow that all diseases are curable in this way. The cardinal mistake of the Christian Scientists and of the believers in faith cure and mind cure is in denying the existence of things which are palpable to the senses; of confounding the phenomena of consciousness with those of volition, and of insisting that all afflictions of every kind are subject to the control of the mind or will.

Modern science is sufficiently eclectic to recognize the great value of mind cure or faith cure in its proper sphere, but the pseudo-science which asserts the power of performing miracles is so narrow and bigoted as to deny the therapeutic qualities of any and every kind of medicine, though demonstrated by years and even centuries of experience. When the time comes for the crucial test, however, those who are not fanatic on the subject will yield their opinion to the skill of others, and if they do not they show themselves devoid of reason and common sense.—*Ex.*

The Gila Monster.

One of these dangerous, lizard-like reptiles was exhibited alive at a meeting of the Academy of Sciences a few weeks since and attracted considerable attention. This reptile is no doubt of a very dangerous character, especially when angered. An Arizona ranchman, by the name of Vail, was recently riding in the neighborhood of his home, when he espied one of these reptiles in the road, and alighting from his horse, killed it as he supposed. He tied the carcass to the back of his saddle and resumed his journey, but soon had occasion to place his hand in the vicinity of the animal, which instantly seized one of his fingers with such a vise-like grip that it could only be removed by having its head literally cut to pieces, which was done by an Indian who accompanied him. The gentleman himself immediately cut the flesh of the finger to the bone, just above the wound, and tied a string tightly around above the cut. He then rode for life to the nearest railroad station, 25 miles distant, where he procured a locomotive and rode 40 miles farther before he was able to secure medical aid. By that time nearly the whole of his body had turned black, and the physician gave him no hope of being able to restore him, although he did congratulate him upon his good sense in refusing to drink whisky at the start as the Indian advised him to do—for that, he said, would have ended his life very speedily. Hard work and the application of the best remedies, at last brought the patient around, however, and he is probably the only man living who is able to relate his own experiences in being saved from the usually fatal bite of a Gila monster.

A REMEDY FOR BURNS.—"A celebrated German remedy for burns," according to the Detroit *Free Press*, "consists of 15 ounces of the best white glue broken into small pieces into two pints of water and allowed to become soft; then dissolve it by means of a water bath and add two ounces of glycerine and six drachms of carbolic acid; continue to heat until thoroughly dissolved. On cooling, this hardens to an elastic mass, covered with a shining, parchment-like skin, and may be kept for any length of time. When required for use, it is placed for a few minutes in a water bath until sufficiently liquid, and applied by means of a broad brush. It forms, it is said, in about two minutes a shining, smooth, flexible and nearly transparent skin."

THEIR WEAKNESS.—The superstition about woman's relative weakness begins to show itself in the training of children. Girls are ludicrously guarded against exercise that they need as greatly as boys, and at every critical period of their life thereafter they pay in suffering for the misguided consideration of those who had their training in hand. The so-called "lady-like" demeanor of girls is a thing to excite impatience. Girls brought up in strait jackets of physical propriety—physical freedom will hurt nobody's "manners"—can never have the grace of deportment, the variety of poise, the readiness in emergency that will belong to girls of liberal physical training.—*Checkley's Method of Physical Training.*

TO REMOVE THIRST.—Paint the tongue of your fever patients with glycerine, says a physician; it will remove the sensation of thirst and discomfort felt when the organ is dry and foul.

IT IS STATED that a system of electric homeopathy has been used with some success in India to cure leprosy.

USEFUL INFORMATION.

WEBSTER'S IDEA OF THE PACIFIC COAST.—It is somewhat singular that a man like Daniel Webster should have entertained such an erroneous idea of the value of the Pacific Coast as his own words show that he did. Less than 50 years ago a bill was brought before the United States Senate to establish a mail route from Western Missouri to the mouth of the Columbia river. Senator Webster opposed the measure as a useless expense and spoke as follows: "What do we want with the vast, worthless area—this region of savages and wild beasts, of deserts, of shifting sands and whirlwinds of dust, of cactus and prairie dog? To what use could we ever hope to put these deserts, or these endless mountain chains, impenetrable and covered to their base with eternal snow? What can we ever hope to do with the western coast—a coast 3000 miles long, rock-bound, cheerless and uninviting and not a harbor on it? What use have we for such a country? Mr. President, I will never vote a cent from the public treasury to place the Pacific Coast one inch nearer to Boston than it now is." After reading the above no one need be surprised that he made the great mistake, in his Webster-Ashburton treaty, of giving away our acknowledged claim to the Pacific Coast from the present northern limit of Washington to the southern boundary of Alaska, while all the country was crying out, "Fifty-four forty or fight!"

THE ELECTRIC LIGHT AS AN INSECTICIDE.—But few are aware of the enormous destruction of insects effected by the electric light. A German entomologist has been investigating and reports that he has found as many as 33,000 are destroyed in one night by a single globe light. Insects must be more plentiful in Germany than here to furnish such an item. But there is no question but that the electric light might be made of great use in destroying many noxious insects which infest our gardens and fields. Mosquitoes, however, and grapevine pests and the pestiferous potato-bug seem to be too wise to be thus ensnared. The chief species which succumb to the wiles of the electric light are gnats and midges.

HANDLING SPARS HERE AND THERE.—The bark William W. Crapo recently arrived at Boston from Washington with a cargo of spars and shingles. Her arrival at Boston created a decided sensation, particularly among the stevedores, when upon examination it was found that her cargo of spars was ugly material for them to handle. Some of the spars were over 120 feet long and 42 inches square, each valued at $300. Capt. Hardy thought he would have to take some of the heavier spars back to Washington, but finally some stevedores were found who managed, in two days, to take out a spar that had been placed in position on the vessel in Washington in as many hours.

RECENT PATENTS.—Among recent patents may be mentioned a knife for separating the loin from the back of pork, an operation which is effected by its means with great celerity; a hand-rest for penmen, consisting of a wire cushion in the form of a coil, which is attached to the wrist, and lessens the wear and tear involved in the act of writing; a skirt elevator, by which "a ladies' skirt may be raised effectively and elegantly with ease and certainty;" and a music rest, by which the music is brought up to a level of the face of a singer, and all undue pressure on the throat from leaning over is avoided.

TO GET RID OF ANTS.—A correspondent of the *Scientific American* says: Buy one-half pound or more corrosive sublimate, powder it very fine and strew the same sparingly on the ground, also in the crevices, nests and trails of the ants, and I guarantee they will leave your premises as quick as they have come. Corrosive sublimate is a deadly poison and should be handled with care.

A CALIFORNIA ROSE BUSH.—The trunk of a rose bush growing in Ventura, Cal., is said to be three feet in circumference, and the first branch it throws out is 21 inches in circumference. It runs over a lattice-work, and, though more than a wagon load of boughs have been removed, it covers about 1200 square feet.

A LARGE BUILDING STONE.—The largest and heaviest building stone ever quarried in England was taken from the Plankington quarry, near Norwich, in February, 1889. It was in one piece, without crack or flaw, and weighed over 35 tons. It was 15 feet long, 6 feet high and 5 feet wide.

ELECTRIC LIGHTS AT THE CAPITAL.—Plans are being perfected to light up the federal buildings at Washington with electricity. It is found to be much cheaper than the present system of gas lighting.

THE REASON WHY firecrackers are always covered with red paper is that red is the festive color in China, and that firecrackers are used chiefly on festive occasions.

THE BUILDER.

Tips for Builders.

Old flooring can seldom be utilized, though I have seen it used for temporary purposes, such as fencing, covering of veranda floors while finishing work on plastering, etc. As a rule, however, it does not pay to take it up carefully and preserve it. Conductor pipes, metallic cornices and sheet-metal work generally can seldom be made available a second time, though all is worth caring for, as some parties may use it for repairs.

Sinks, wash-basins, bath-tubs, traps, heating appliances, grates, mantels and hearthstones should be moved with care. They are always worth money, and may be used in many places as substitutes for more inferior fixings.

Marble mantels require the most careful handling.

Perhaps the most difficult fixings about a house to adapt a second time are the stairs. Yet I have known where a man has so managed to put up new buildings that the old stairs taken from another building just suited. This may have been a "favorable accident," but the initiated reader will understand him. Seldom such accidents can occur.

Rails, balusters and newels may be utilized much easier than stairs, as the rails may be lengthened or shortened to suit variable conditions.

Gas fixtures should be cared for and stowed away in some dry place. They can often be made available, and are not easily renovated if soiled or tarnished.

Never send old material to a mill to be sawed or planed; no matter how carefully nails, pebbles and sand have been hunted for, the saw or planer knives will most assuredly find some you overlooked; then there will be trouble at the mill.

Have some mercy for the workman's tools. If it can be avoided, do not work up old stuff into fine work. If not avoidable, pay the workman something extra because of injury to tools.

Don't grumble if you do not get as good results from the use of old material as from new. The workman has much to contend with while working up old nail-speckled, sand-covered material.—*American Builder.*

BRICK VS. FRAME DWELLINGS.—Nothing, says the *Clay Worker*, is more to be deplored than the relative increase of the number of frame dwellings in our large cities. There are acres of kindling-wood construction, comprising the woof and web of all but the centers of our large cities. Through the improvement in the quality of clay products, and the constantly increasing cost of wood as a building material, together with other natural and well-known advantages leading to the use of brick, it is to be expected that there will be a revulsion of feeling favorable to brick houses within the near future. A frame dwelling is necessarily a temporary structure. The decorative features are marks for decay and degeneration. The more ornate a frame house is made, the more temporary is its character. The waste of money in these insecure temporary structures is frightful to contemplate. If for no other reason, people should build of the more substantial material because of the danger from fire. We have startling examples of this every day in the loss of life and property. Yet the spirit of shoddyism, sham and show is a part of so many of our home-seekers that the increase of these inflammable piles is yet apparent. The reduction in the cost of money, in the rate of interest, should in itself suggest better houses, better dwellings of brick. The cost of building a brick house is less than it was a few years ago, when all decorative work had to be done in stone at a great expense. Now the ornamental effects in a brick house are secured at a much less expense through the terra cotta and ornamental brick which can be produced more economically than stone and are more durable and beautiful as well.

LEGAL ASPECTS OF PHOTOGRAPHING BUILDINGS.—An excellent idea is suggested by an architect who writes to the Pittsburg *Real Estate Record* as to the benefit of photography in building operations. He remarks: "With high buildings arises a question of good foundations, especially when they are built alongside of old buildings two or three stories high. The greater weight of the new and high building is apt to crack the old building and damage it, and great care should be used in building up to prevent the settling of the new building from injuring the adjoining property. I suppose that for any damage done to the adjoining building the proprietors of the new building will be responsible, so I would recommend not only care in the foundation of the new building, but that the adjoining buildings be photographed to a large scale before any work is done on the new building, so that their condition might be on record in the event of a claim for damages. These photographs should be taken under the charge of one well acquainted with building, and should be not only the back and front, but the sides and parts of the buildings adjoining the new one. Often there are cracks in those side walls and they ought to be photographed. One may laugh at the idea of photographing a crack, but it is sometimes very necessary, and I have seen the owner, who was claiming that the new building had damaged his property, look very queer when a photo of that same crack was shown, proving that it was there before the new building was erected."

ELECTRICITY.

Electric Railways.

We clip the following from the editorial columns of London *Iron*. Though probably collated from American journals, the editor of *Iron* gives it his editorial sanction:

There is every probability that electrical railways will be the railways of the future, and a little thought will fully demonstrate this. According to Captain Eugene Griffin, who recently lectured on the subject at the Franklin Institute, Philadelphia, the success of electrical propulsion has been established beyond a question. It is only a matter of time, and that a short time, when it will replace the horses on the majority of street railways. It is only a matter of time, a somewhat longer time, perhaps, when it will be the propelling power on all elevated roads, for elevated railways possess ideal conditions for the application of electricity. It is within the bounds of possibility that steam roads will be worked by electricity; certainly this power offers many advantages for the suburban traffic in the vicinity of large cities. The possible utilization of hitherto neglected water-powers will be one of the features in determining the extension of electrical propulsion in this direction. Already we see the beginning. Longer trains are requisite to meet the increasing demands. The limit of the capacity of the present locomotives has been reached. Increased weight in the locomotive means an immense expenditure for strengthening or practically rebuilding the roadway. Cables are not feasible, as the strain on the grip would not permit of long trains, and it would be difficult to combine speed and safety with any considerable increase in the number of trains. Cables would not permit of satisfactory switching arrangements at the termini and elsewhere. Electricity offers the best solution. Equip each car with motors. Flexible electrical connections can easily be made from car to car, as is now done on surface roads, to light the tow cars, and the whole train controlled by the driver on the front platform of the leading car. Electric, vacuum or air brakes can be used in the same way. It matters not how many cars we have in a train—one or fifty. Each car adds its own power, and all work together. There is no dead weight to pull, as in the case of the locomotive. The passengers themselves furnish the weight for traction. The switching arrangements present no difficulties whatever. The motors can be reversed and run equally well in either direction. The train can be controlled from either end, and any increase or decrease in the number of cars will not affect the controlling mechanism.

New Electric Roads.

By the close of the present summer there is good reason to believe a large number of new electric roads will be put in operation. This supposition is referred to by *Bradstreet's* as follows: "The activity in street-railway matters this spring has been unprecedented. More roads are building than ever before. More roads are projected. More roads are changing their motive-power. More transfers of ownership have been made or are in progress. The chief cause of this is the spread of the belief in the economy and general desirability of the electric motor." The importance of these improvements in street car facilities in a city is referred to by a Cleveland paper, which, in commenting upon the electric railways of that city, says: "Cleveland has had its share of all this, and here, as elsewhere, the great progress made during the last few months toward general rapid transit on street railways has had a marked effect in the building up of outlying residence territory and in checking the tendency toward tenements and apartment houses. For this reason it is a most beneficent change in the conditions of life in large cities. The effect of better street-railway facilities is more homes—in the best sense of the word, more fresh air and green trees for people of modest means, and a greater aggregate of comfort and happiness."

WASTEFUL RUNNING OF ELECTRIC LIGHTS.—In the use of incandescent lamps it is too frequently the habit to run them at a higher candle-power than they are rated at, and higher than they will stand for any considerable length of time. While an incandescent lamp increases considerably in candle-power with a slight increase of current, the life of the lamp is decreased in a much greater ratio, for a lamp that will give 16-candle power at 110 volts will give 30-candle power at 120 volts. While this very nearly doubles the candle-power with an increase of less than ten per cent of current, the life of the lamp will be decreased nearly 90 per cent. As a lamp operated under conditions similar to the above would have a capacity of only about 30 per cent of what it would be if operated under conditions more favorable to long life, it is easy to be seen that running lamps above their rated candle-power is an expensive way of getting more light. When more light is required, it is much more economical to increase the number of lamps or use lamps of a higher candle-power. In either case, care should be taken that the conductors are capable of carrying the increased amount of current without overheating.—*Ex.*

Passing Events.

Wednesday of this week was the first day on which the Government has purchased bullion under the new Silver law. It is said that the largest offers to the Government from New York were made at 113¾. Ahout 1,000,000 ounces were honght at ahout $1.1254.

The new cruiser San Francisco, whlch has been tried several times in the hay, will he soon ready for her test trip. This oruiser, built in this city, is a fine vessel and her performances thus far indicate that ahe will make high speed and he in every way satisfactory.

Preparationa for the comlng Mechanics' Fair and for the celebration hy the Native Sons of the 40th anniversary of the admission of California into the Union are going on satisfactorily, and it is expected both events will bring many thousands of people to San Francisco ln September.

A great deal of interest is manifested jnst now in the new mining districts in Washington, and prospectors are husy in all directions. Most of the region has heen neglected hy miners, hut it is prohable aeveral good camps will be developed this winter.

W. H. CLARK of San Diego, who lately started a line of steamers between San Diego, the Hawaiian Islands and San Francisco, says the Hawaiian Congresa has introduced a bill giving the line a subsidy of $24,000.

Assays and Mill Losses on the Comstock.

An anslysis of the quarterly bullion reports of the mines now producing ore on the Comstock lode is full of interest to stockholders therein, though showing a condition of affairs that is not calculated to encourage them or induce others to purchase shares. Below is given a tabulated statement whioh shows the results of the working for the last qnarter:

	Ore Extracted Tons.	Gross Yield.	Costs and Charges.	Profit.	Loss.	Average Yield per ton as per Bullion Report.	Average Pulp Assay for quarter.	Per cent of Pulp Saved.
Con. Virginia and California	35,485	$512,370.27	$402,876.01	$20,432.56		$14.60	$ 3.84	65 85-100
Justice	2,253	31,375.10	31,237,361.44	46,426.58	98,639.41	13.92	2.80	65 76-100
Crown Point	6,065	87,303.49	3,659.09			14.26	35.25	85
Overman	4,233	76,045.32	2,487.31			17.96	21.50	84 7-10
Alta	4,250	40,138.38	57,554.24	16,303.37		9.44	23.05	41 82-100
Cholar	6,881	97,914.04	98,043.20		817,215.86	14.05	29.17	76 5-10
Savage	6,063	90,912.00	97,705.76		152.22	16.95	21.85	65 2-10
Hale and Norcross	14,238	135,749.31	129,310.65	6,702.24	14.90	9.57	71 8-10	
Yellow Jacket	4,801	65,508.38	71,160.71	5,555.33	13.85	21.50	64 41-1 0	
Challenge	760	10,898.28	28,128.06	17,720.78	13.96			
Confidence	1,292.66	18,942.63	18,942.63	17,649.97	12.20			
Con. Imperial	2,736.21	29,362.45		26,556.27	13.90			
Totals	87,908	$1,375,102.19	$1,237,361.44	$46,426.58	$98,639.41	$14.60	$ 3.84	65 85-100

As will he seen by reference to the table, 35,485 tons of ore from the Consolidated Virginia and California produced but $1184 25 more profit than 4233 tons from the Overman, the ore from the former being worth (according to the average quarterly pulp report) $1.09 per ton more than that from the latter.

This difference is dne to the fact that the mills running the Con. Virginia ore saved 19 35-100 per oent less of the pnlp assay value of the ore than the mill running the Overman ore. In other words, the Con. Virginia crnshed over eight timea as much ore as the Overman and produced only $1184.25 more profit, the ore from the Con. Virginia being worth $1 09 per ton more than the Overman ore.

In the Alta Mining Company's returns there is a still greater differenoe. They saved but 41 22-100 per cent of their pnlp assays and hrought the company in deht $17,215.86. Their average pnlp assay for the quarter waa $23.05 per ton, which was $1.80 per ton more than the Overman, and they milled 27 tons more ore.

When it is understood that 85 per cent of the pulp assays can he easily ohtained, the frightful loss to stockholders oan be seen. If the mills running the Justice and the Overman ores can save 85 75-100 per cent and 84 7-10 per cent respectively, there is no good reason why mills running the ore from the other mines cannot do the same. It must be nnderstood that the tailings from the ore goes to the profit of the mills and is lost to the stockholders. To give an idea of what these losses are, they have heen put into figures:

To Con. Virginia and California, the difference between 85% and 65 35-100%.....	$154,424 30
Savage, difference between 85% aod 68 2-10%	22,698 24
Hale and Norcross, difference between 85% and 71 8-10%.....	34,405 80
Chollar, difference between 85% and 76 5-10%	11,232 71
Alta, difference between 85% and 41 22-100%	42,983 40
Crown Point, difference between 85% and 72%	25,298 40
Total.....	$291,042 85

This went to the profit of the mills. In addition to this they received $7 per ton for milling 87,303 tons of ore—$611,121—whlch added to the above amount makes the snm of $902,. 163.85 which went to the mill-owners for the quarter.

It will he noticed that in no instance is the assay value given of the ore at the various mines before dumpling it into the chutes for the mills to work on. The stockholdera of the various companies have the privilege of guessing at that, but that the large amonnt given above is not all that drops into somebody's pocket at the stockholders' expense, is shown hy the sworn testimony of the superintendent of two of the chief ore-produoing mines on the Comstock. In answer to the qnestion whether he fonnd any difference between the mine and mill assays (before ornshing) of the ore delivered to the mills by the two companies he represented, he answered: "Well, they differ, perhaps, $10 to $12 per ton; they differ as all mines differ. There is no difference from any other mines. The history of the whole business is that there is $10 or $15 a ton difference hetween the battery samples and the car samples; in other words, we never get within $10 or $15 of what our car samples call for." (This testimony is signed by the superintendent mentioned.) If this gentleman makes no mistake, then the stockholders are out $12 50 per ton, less 15 per cent more on 87,303 tons, or $927,. 599, whloh added to $902,163.85 makes the enormons sum of $1,829,762.85 which went to the mill-owners of the Comstock during the quarter ending Jnne 30, 1890. Not one mine paid a dividend out of the earnings for this qnarter.

Is it surprising with this showing that the mill-owners of the Comstock are the millionaires, while the stockholders are its psupers?

The Alta, Chollar, Savage, Hale and Norcross, Jacket, Challenge, Confidence and Con. Imperial show losses. In at least five of these companies the stockholders will be assessed to take out ore which if handled properly wonld pay dividends. The figures show a loss of $52,259.25 on 87,303 tons of ore, whereas if it had been worked to 85 per cent of the pulp assays (without considering what the ore assayed at the mines), the same ore wonld have shown a profit of over $250,000.

Further comment is unnecessary. The figures speak for themselves.

Mineral Lands in California.

It did not take the jnry very long last week to decide the qnestion of mineral or agricnltnral land in the Eagle Bird mine case, and the decision is one that relieves miners all over the country. Purchasing so-called agricultural land on odd sections from a railroad company was a pretty easy way for men to get hold of valnable mining property, and if the aystem could have heen maintained many men would have had to buy their own mines from somebody who came along a dozen or so yeara after they located said claims.

However, this decision pnts a stop to that practice, for the present at least. The fact of the matter is, that the inquiries as to character of land are entirely unsatisfactory. A few men who do not pretend to know mineral ground when they see it, swear that so far as they know there are no minerals, and immediately the land becomes agricnltural. No tronble at all is taken to get adverse testimony or that of an expert. Unless aome one is personally and directly intereated in the tract as a miner, no one appears to conteat the nsually worthless testimony offered. In this way within the past few years large tracts of land have been taken up nnder agricnltural title where there are plenty of mining claims or proapecta. No one county in the State is free from this practice, as we have before ahown in the PRESS.

When in addition, the railroad companies also claim the minerals on odd sections, it narrows down the field of the prospector aud miner to very small proportions. The mining pnblic is to be congratnlated on the result of the Eagle Bird case in the courts, since it settles a question which clouded titles to many hnndreds of mines, developed and nndeveloped.

WATER TRANSPORTATION.—Thomas J. Vivian of San Francisco has heen appointed Special Agent of the Eleventh Censns to collect the statistics of water transportation on the Pacific Slope, the Territory of Alaska excepted. All correspondence which managing owners of vessels have heretofore had with the Census Office has heen turned over to Mr. Vivian, and all further correspondence may he carried on with him.

A PATENT CONTROVERSY.—The suit of F. A. Huntington against the Risdon Iron and Locomotive Works has heen on trial hefore a jury this week in the United States Circuit Court. Hnntington seeks to restrain the defendant from infringing on a quartz mill patent, and to recover $50,000 damages.

An Electrical Exhibit.

The Mechanics' Fair this year will open on Sept. 18th and close Oct. 25th. Efforts are being made to canse this to be the most attractive exposition ever held here. A special featnre will be a separate electrical exhibit, including the varied applications for heat and power. The entire Grove-street side of the pavilion has been set aside for that purpose, besides room for the dynamos in the machinery hall. This will be the first time that snch an exhibit has been seen on this coast. The electrical companies are expected to make exhibits. There will be displays of arc and incandescent lights, motors, batteries, machinery and various forms nf electrical apparatus. A special attraction will be a column of light eight feet in diameter and 26 feet high placed in the center of the main aisle, the same as shown at the Paris Exposition and lately at Lennox Hall in New York, where for a number of weeks it drew thousands of visitors.

The United Edison Manufacturing Company has agreed to display the models and machines of all the electrical inventions of Edison, including the telephone and phonograph.

The California Electric Light Company is now engaged in designing some new and startling featnres of the power of electricity, as well as a display of arc and incandescent lights.

The Electrical Engineering Company has also consented to make a display of new improved motors and nther applianoes invented hy Professor Keith. These, together with a display promised by the Thomson-Houston Electric Company, the Heisler Long-Distance Incandescent Light Company and the Westinghouse Electric Company, should make an excellent display.

We suggest to the management, in connection with the application of electric-power to mining, that they might have a stamp-mill run by electricity, carrying the power say three or four miles by extending the wires round and round the building. A mill, pumps, hoist, drills, compressors, etc., could he thus shown at work, and exhibit in a practical way what electricity can do for mining. It would not be difficult to arrange this, and it would attract great attention. Miners read about snch things but have no opportunity to see them at work, there being only one in this State. Such a plant, in a central place like San Francisco, would bring many visitors.

California Ores and Minerals.

The secretary of the State Board of Trade haa issued a special circular to the mining counties asking them to represent their sections in the traveling exhibit of "California on Wheels" by sending specimens of ores and minerals. An exhibit is also wanted in the Board of Trade rooms in San Francisco. It is unfortnnate that there seems no other way of repreaenting the mining industry than by ores and minerals. A county with only half a dozen partly developed mines can often make as fine a display as one with some hundreds. It would be much better to have relief maps showing the locations of mines that are being worked, so colored and formed as to indicate the extent of the industry in any one section or region.

The mining community is asked so often, for many purposes, to contribute specimens, that it becomes a nuisance in time. The State Mining Bureau, with its fine, large collection and countless duplicates, could easily arrange a typical collection of ores and minerals, properly located and identified, and lend it to the Board of Trade for the traveling exhibit. Both institutions represent California, and one could easily help the other.

It is suggested that the State Board of Trade see the trustees of the Mining Bureau and get the latter to arrange a small collection suitable for sending around the country with the "California on Wheels," so that mineral as well as agricultural resources would be properly represented. This would save the time and trouble necessary to make collections from the counties and answer the purpose of advertising the mines just as well.

IT IS said that D. O. Mills and J. P. Jones have made extensive purchases of mining properties in the Death Valley region, and that they will in the near future inaugurate operations on a large scale.

Western Lead Smelting.

At Argenta, Beaverhead county, Montana, the St. Louis & Montana M. Co. made in 1866 the first serious attempt at regular smelting in the few Western Territories. Up to that time the hackwooda hearth, the Scotch hearth and its improved congener the American hearth, such as were to be found in the lead mines of Illinois and Missouri, were the only forms of smelting apparatus to be found in the far West. The St. Louis & Montana Co. adopted the Freiberg double-shaft furnace of the type used in Germany for the reduction of lead ores. Figs. 1, 2 and 3, taken from the drawings made at Freiberg, in Saxony, Germany, give all the necessary plans of such a furnace. Fig. 1 represents a section through the breast from front to rear; Fig. 2 represents a section through the furnace at right angles to Section 1; Fig. 3 represents a ground plan of the hearth with the accompanying tap basin and tap canal. The following description was contributed to the Eighth Annual Report of the State Mineralogist by W. S. Keyes, a trustee of the State Mining Bureau:

The pillars inclosing the furnace were made of granite or gneiss, having a face of over three feet, and alone contained material almost sufficient for the whole of a modern furnace. A fire-brick lining extended from the ground floor of the furnace to a point about one foot and a half above the tuyeres. It will be observed in the section, Fig. 2, that a partition wall extends from the top of the furnace downward to a point about two and a half feet above the level of the tuyeres. This wall rests upon an arch sprung from front to rear of the furnace, and was made of common brick in the upper portion and of fire-brick in the lower courses. The object of this wall was to insure a uniform descent of the smelting mixtures. The bottom or hearth of the furnace was composed of a mixture of charcoal or coke-dust and clay, well tamped in, beneath which are deposited a mass of rubble, which serve as an exit for the moisture contained in the brasque. A hole was cut through the hearth lining to the exterior tap basin. The furnace could smelt from six to ten tons in 24 hours. The Montana ores to be treated consisted of oxides, carbonates, sulphates and sulphurets of lead, usually found in the magnesian limestones of the far West. They afforded an ample percentage of lead for smelting, and were more than usually rich in silver, 200 and 300 ounce ores not being uncommon. They did not require any considerable amount of iron for fluxing. The price paid for smelting was $100 per ton. Nevertheless, on account of breakdowns and delays, bad charcoal, inexperienced workmen and an irregular supply of ore, the works were not a financial success, and, under the advice of the writer, were closed down and smelting discontinued. The work-lead or base bullion obtained was repelled in a large German cupel hearth, and 30 tons were put through in three days and two nights. The resulting silver was broken up, cast into molds and shipped to its destination.

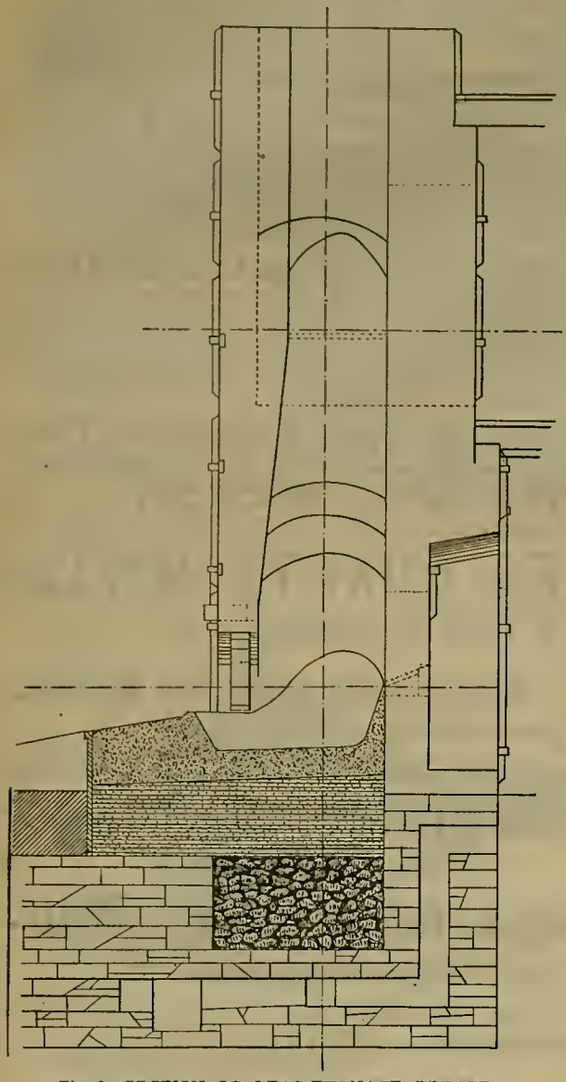

Fig. 1.—SECTION OF LEAD-FURNACE BREAST FROM FRONT TO REAR.

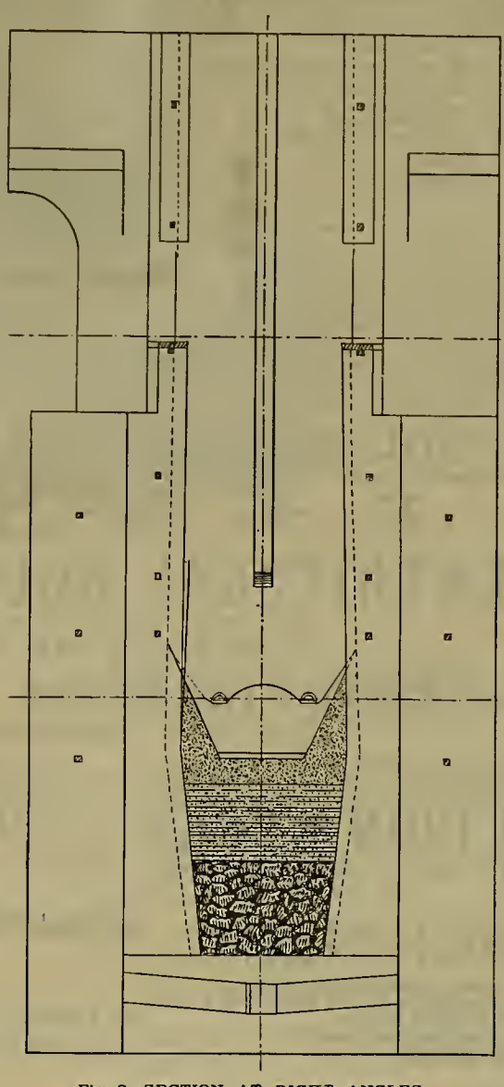

Fig. 2.—SECTION AT RIGHT ANGLES TO FIG. 1.

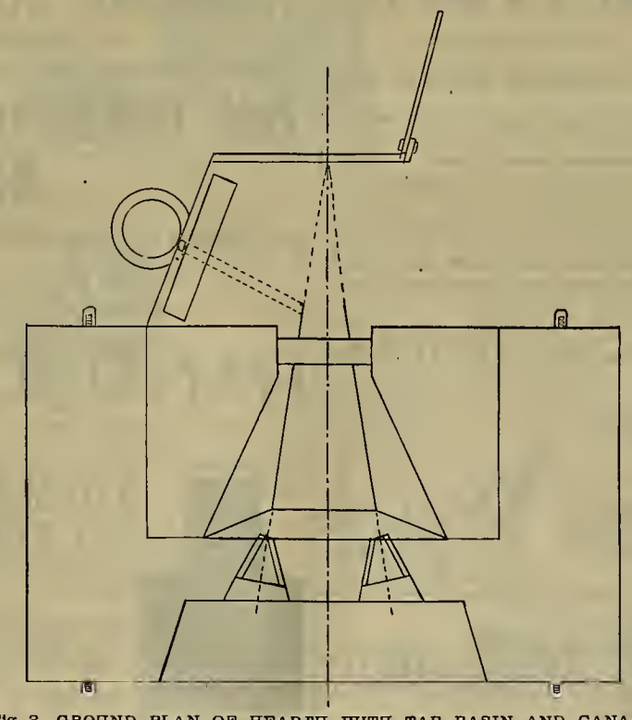

Fig. 3.—GROUND PLAN OF HEARTH WITH TAP BASIN AND CANAL.

In 1867 the Trinity and Sacramento Mining Co. acquired certain mines in the vicinity of Oreana, Nevada, and erected works. The ores were docile, but contained a large amount of antimony. A fair average, perhaps, would be some 30 per cent of the latter metal. Much of the ore was rich, in value from $80 to $200 in silver per ton. The furnaces were somewhat similar in form to that already described at Argenta; they were, however, 30 inches square, and were capable of reducing in 24 hours about eight tons of ore. The base bullion so obtained required a preliminary calcination before it was repelled. This calcination was performed in an iron pan 13 feet long, 5½ feet broad and 10 inches deep, with an initial charge of 12 to 15 tons. As the lead was purified, an additional amount was added until from 20 to 25 tons would be more or less thoroughly purified. This process required about ten days. The lead was then repelled in a long cupel hearth with movable tests set upon wheels. The test was made of an oval iron frame, five feet long, about 40 inches wide, and was filled with a mixture of bone-ash and willow ashes. So impure was the work-lead as it came from the smelting furnace, that a bar, when cold, if carelessly let drop, was often broken in two. This repellation of the lead *in situ* was rendered necessary from the fact that the overland railroad had not yet reached Oreana, and the long haul to a market wholly ate up the value of the lead. As soon, however, as the railroad was completed to this point the base bullion was sent to San Francisco to be refined.

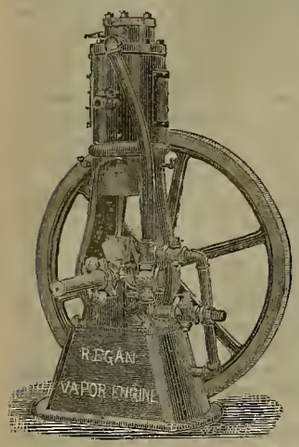
In 1870 several smelting furnaces, mostly small, were built at and near Shermantown, Swansea and Hamilton, White Pine county, Nevada. One of these, situated at Swansea, and originally built by Joseph Moshemier of San Francisco, was under the charge of the writer and Mr. O. H. Hahn. The smelting ores of White Pine county at and near Hamilton, were eminently basic. They were poor in silver, but abundant in lead carbonates, and in so far desirable and easy to treat. Owing, however, to an absence of quartz in the ores themselves, and the difficulty of obtaining alliceous ores for fluxing purposes, their reduction gave rise to the formation of "anws" innumerable, which hindered the smelting and often necessitated the blowing out of the furnace. These works produced, in the course of a few months, above 1000 tons of base bullion, and resulted in a gross financial loss of $30,000, after which experiment the furnaces were closed down and smelting abandoned. A like fate befell all the smelting furnaces in the vicinity of Shermantown and Swansea. There was no possible profit in smelting. The ores were exceedingly poor, and the owners of the mines asked such a price for them that the furnaces were unable to exist.

A curious fact in connection with smelting at this place may here be noted, viz., the behavior of mountain mahogany charcoal in the blast furnace. This wood, as is well known, is of a very firm, compact texture, and in the process of carbonization becomes thoroughly burnt out, so to speak; and as a result, when this charcoal is put into the furnace and the charge thrown upon it, it becomes crushed to an almost impalpable powder, so that the blast cannot force its way through, and strange as it may appear, this fuel actually put the fire out. So pressing was the need of silicious ore for fluxing that Mr. Hahn and the writer cast about them for a substitute. They hit upon the use of the clay slates, which were quite abundant in the neighborhood, and this was, as far as the writer is aware, the first attempt to make aluminate instead of silicate slags. The experiment proved a success.

A DEMAND FOR GOLD.—Assistant United States Treasurer Jackson reports an unusual demand on the Sub-Treasury for gold, many people bringing United States securities and converting them into the yellow metal. Mr. Jackson does not know whether there is any particular significance in the movement in connection with the recent silver legislation; but if it is general in the East, as well as here, he thinks that it may have been suggested by the enemies of silver.

SOME 700 gold bars, worth in the aggregate $4,000,000, were shipped to Europe from New York, one day last week.

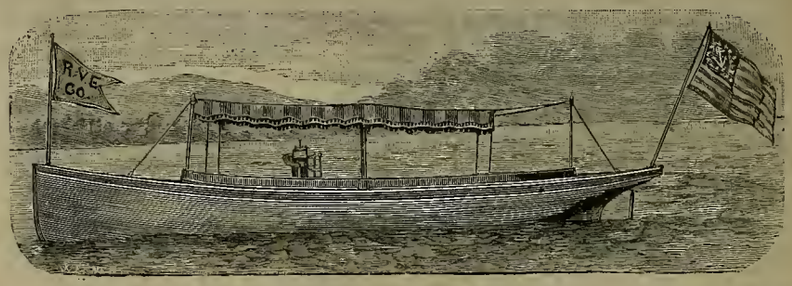
REGAN VAPOR ENGINE.



NO BOILER! NO FIRE! NO STEAM!
Simple, Compact and Cheap.
No Fire or Flame. Started Instantly without Even a Match.
No Ashes! No Explosion! No Engineer!
FULL POWER OBTAINED IMMEDIATELY.
The Moment Engine Ceases to Run, all Expense Stops.
NO DANGER.
Horizontal, Upright and Marine Vapor Engines and Launches,
Three fourths to Fifteen Horsepower.
From $175 to $1200.
Send for Our Large Illuetrated Catalogue.

GEORGE HAAS, 824 Market St., Phelan Building, } SAN FRANCISCO, Feb. 21, 1890. }

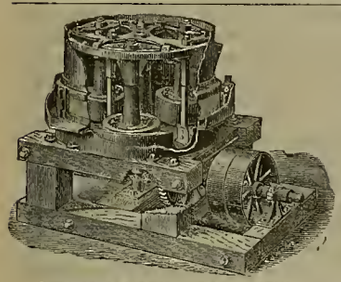
REGAN VAPOR ENGINE CO.—Gentlemen: The 2 H. P. Engine you put up in our factory last November, has given satisfaction beyond my expectations. It do s my work better than than those two Electric Motors did, with scarcely any expense for gas. I paid the Motor Company $25 per month for power, while the Vapor Engine has cost me but $2 per month so far. But, be it understood, I have not used the Engine as much as in summer, but the cost of motor would have been all the same, making a saving of $69 in three months. I am satisfied the Engine will pay for itself in less than two years. I use it for freezing cream, run three fans, cocoanut grater, etc.
Yours truly, GEO. HAAS.



Regan Vapor Launches

The uece for small steamboats and launches are innumerable; they are convenient and serviceable for transportation, and are a cource of pleasure for those who are fond of sailing. But many have been deterred from purchasing such boats, because of the trouble and inconvenience of using coal, and the necessity of obtaining a Government license, engineer, etc. Our motor does away with these objections. The small space taksn up by our engine in the boat **gives more room**; the boat will seat twice as many persons as one the same size fitted up with a steam engine. It takes only **two minutes to get under headway**, and can be stopped when running at full speed within the length of the boat, this reverse motion being instantaneous and effective. We carry in stock six regular sizes of hulls, from 18 to 33 feet in length, our models being the best that can be obtained, and built in the strongest and most substantial manner by Thos. Kane & Co., Racine, Wis.

REGAN VAPOR ENGINE CO., 221-223 First St., San Francisco, Cal.



Centrifugal Roller Quartz Mill.

F. A. HUNTINGTON.

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, Aug. 14, 1890.

General trade the past week has been fairly active for the season. The high prices ruling for farm products and the general activity in all mining districts, together with wage-earners well employed at good pay, inspire confidence in the future.

The local money market is fairly easy. The call for funds for crop purposes continues free, while remittances from the interior show an increase.

The steamer Belgic, hence Aug. 12th for China, took out the following treasure: Mexican dollars, $259,013; gold coin, $20,695.

MEXICAN DOLLARS—The market has been quite active at 88 to 88½ cts. At the close it looks as if another advance will be made at an early day.

SILVER—The market here held to $1.11½ up to Wednesday, when quotations were withdrawn. All large offerings have to be made direct to the Department at Washington. The action of the Department in keeping prices paid for silver a State secret is very generally condemned as being in the interest of Wall street and other speculators. It is contrary to the spirit of our Government and should not be tolerated, for it makes the Department a speculator in silver, which was not intended under the present law. In England the price paid by the Exchequer is made public, and if it should be repressed the House of Commons would by vote inquire into the reason for suppressing the information.

Senator Teller has introduced into the U. S. Senate a hill calling for the free coinage of silver when the price reaches par. This is a move in the right direction, which should be passed by Congress.

The advance in silver abroad and its sensitiveness to outside influences are confirmatory of the position taken by this paper nearly one year ago that the supply is light.

The London market is higher to-day, being quoted at 51 5/16d. It is reported that the Mint paid on yesterday over $1.13 per ounce for silver.

The Mint's counter rate is $1.12½ for small quantities. For large quantities selling offers have to be submitted to the Department at Washington.

QUICKSILVER—The market is barely steady. The demand is said to be fair. Receipts the past week aggregate 348 flasks, and exports by sea, 16 flasks to Mexico.

BORAX—Receipts the past week aggregate 2052 centals. The demand continues fair, with the market steady.

LIME—Receipts the past week aggregate 3975 hhls. The home demand is reported to be good, while the shipping inquiry is light.

COKE—Imports the past week aggregate 1680 tons from Cardiff. The market continues easy.

IRON—Imports the past week aggregate 583 tons from Cardiff. The local market is firm with a fair consumption reported. Eastern and European advices, while reporting a dull market, state that there is a strong undertone.

TIN—The market is easy for both plate and pig. Late English cables report an active and strong market for both pig and plate. The advance in silver is in favor of higher prices abroad for pig.

COPPER—The market has held easy throughout the week. The East reports trading fair, with the market lower. A London cable to the *Iron Age*, Aug. 7th, says: Statistics show large supplies and deliveries last month, with a decrease of 891 tons. The amount held by the Societe des Melaux is now only 2000 tons, against 179,000 tons 16 months ago. Transactions in furnace material have been quite heavy latterly.

COAL—Imports the past week aggregate as follows: Seattle, 4008; Tacoma, 6100; Nanaimo, 2320; Departure Bay, 1945; Philadelphia, 399; Union, 4300; Port Townsend, 1100; Coos Bay, 700; total, 20,872 tons. The tonnage to load, loading and on the way from Australian ports is as follows: Newcastle, N. S. W., 53 637 tons; Sydney, 11,201 tons. Late cablegrams from Australia report tonnage scarce, and as the above coal is said to be cared for, our market for loading is strong at a slight advance. The strike at Wellington is still on, but the mines are turning out coal with non-union miners. The output of coal on this coast is steadily increasing, but the demand is also increasing.

Eastern Metal Markets.

By Telegraph.

NEW YORK, August 13.—The following are the closing prices the past week:

	Silver in London.	Silver in New York.	Copper.	Lead.	Tin.
Thursday	50 13-16	1 11½	$16 90	$4 47½	$20 90

THE total yield of the Con. California and Virginia mine for the ten months of the current fiscal year ended August 1st was 106,796 tons of ore, producing bullion valued at $2,043,976. Out of this sum, $270,000 was disbursed in dividends to shareholders.

Mining Share Market.

The mining share market, the past week, while steadily setting off, has not sunk to as low prices as many well-informed operators look for. There is nothing in the situation to warrant the present depression, but, on the other hand, everything to inspire confidence. The mines never looked so well as they do now, with their miles of drifts, crosscuts, etc, running in all directions so as to prospect and develop the mines at less cost. The stealings that have been going on for years will soon be a thing of the past. This opinion is grounded upon the fact that never before was there an organized move to fight for reform—honest management of the mines; and this fight is being waged by the Mining Stock Association of this city. When the reform is brought about, every assertion made by the MINING AND SCIENTIFIC PRESS will be verified regarding the rich ore in some of the mines.

The better informed operators claim that the present move of the ring to depress the stock market is nothing more nor less than a big bluff so as to convince outsiders that there is nothing in the mines, so as not only to keep outsiders from buying but force them to sell the few stocks they have; and in carrying out this program large lines of marginal stocks have been sold by brokers, which, of course, *were* owned by outsiders, but are *now* owned by the ring.

Dealers must be careful in crediting reports of parties floating stocks of any mines not listed on the stock exchanges, that Commodore Flood and Col. Mackay control the mine, and that it is the coming bonanza.

A few years ago the late Archie Borland was a big trump to send prices of stocks up or down; then came Levy, and after him the ring played Col. Mackay, hut he has failed to draw; then Finlay of the *Post* was sent to the front, but this was a boomerang, and now, so rumor states, Commodore Flood will visit the Comstocks probably as a drawing card.

Overman's hullion output for July aggregated nearly $38,500, and Crown Point's $38,808. The former mine added to its cash reserve, while the latter company after paying all debts carried over a cash balance. Chollar's, Savage's, and Hale and Norcross' July bullion outturn are not given. Belcher's bullion outturn in last month aggregated $15 953.

Crown Point pays $7 a ton for milling ore, as does Belcher, hut the former gets a rebate of $1 a ton, while the latter does not.

Private news from the Comstock mines is hard to get, or, at least, that which is reliable, further than has heretofore been published. Official letters received yesterday (Wednesday) report that in cutting out a station in the north drift on the 1300-foot level of Savage they were in good ($40 to $60) ore, having a width of 18 feet. Crown Point is milling ore, but the battery assays are low. In Belcher active and favorable prospecting work is under way. The battery assays of the ore milled fell below $23 a ton. The repairs to the Hale and Norcross shaft will he completed this week, and the hoisting and milling of ore he resumed. The superintendent of Kentuck reports the prospects favorable for finding a body of pay ore on the 1000-foot level.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, $3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

ALAMEDA M. & M. CO., Aug. 12. Capital stock, $100,000. Directors—J. T. Landregan, J. A. Hall, P. Mauve, W. C. Wright and James Shea.

CALIFORNIA CONTRACTING CO., Aug. 12. Object, doing general contracting work. Capital stock, $100,000. Directors—J. C. Robinson, J. H. Harbour, H. T. Jones, Wm. Liddington, M. R. Twormy.

PACIFIC BONE, COAL & FERTILIZING CO., Aug. 12. Capital stock, $200,000 Directors—Thos. Brown, A. Haas, F. H. Eichbaum, A. Haraszthy, S. A. Haas.

PEACE MAYNARD CO., Aug. 13. Object, to deal in real estate. Capital stock, $150,000. Directors—J. A. Maynard, H. L. Peace, A. Gould, Samson Moore and Wm. Hayward.

CALIFORNIA GASLIGHT & FUEL CO., Aug. 13. Capital stock, $10,000,000. Directors—W. H. Murray, Geo. E. Barnes, H. P. Cohen, Geo. Hazleton, W. B. Ewer, J. L. Boone, Francis Moore, W. C. Quinby and H. B. Smith, Jr.

BLUE LAKES WATER CO. (Oakland). Aug. 12. Object, to supply water from the Sierra to Stockton, Oakland, Alameda and other places. Directors—T. G. Phelps (President), V. D. Moody of Oakland (Vice-President), Daniel E. Hayes, J. W. Smith of Oakland, General R. W. Kirkham, H. D. Bacon of Oakland, Thomas Bell of S. F., A. T. Hatch of Solano, S. A. Marshall of S. F., F. K. Shattuck of Oakland and J. S. Emery of Oakland.

TIF. HAUSKINS and George Lovelock, Jr., have sold the gypsum deposits, which are situated about five miles east from Lovelock, Nev. The purchasers are San Francisco men and the consideration is $6000.

Assessment Notices.

GOVER MINING COMPANY—LOCATION of principal place of business, San Francisco, California. Location of works, near Dutch Town, Amador county, California.

Notice is hereby given that at a meeting of the Board of Directors held on the 14th day of July, 1890, an assessment (No. 2) of twenty-five cents (25c) per share was levied upon the capital stock of the Corporation, payable immediately to the Secretary, at the office of the Company, 13 and 15 Fremont street, San Francisco, California.

Any stock upon which the assessment shall remain unpaid on Wednesday, the 20th day of August, 1890, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on SATURDAY, the 6th day of September, 1890, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

CRAY DEW, Secretary.

Office, 13 and 15 Fremont St., San Francisco, California.

DELINQUENT SALE NOTICE.

GRAY EAGLE MINING COMPANY—Location of principal place of business, San Francisco, California. Location of works, Placer county, California.

Notice—There are delinquent upon the following described stock, on account of Assessment (No. 18) levied on the first day of July, 1890, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Cert.	No. Shares.	Amt.
Bogart, O H, Trustee	423	350	$ 21 00
" " "	424	650	30 00
" " "	447	5,000	300 00
" " "	488	105	6 30
Barrows, A W, Trustee	537	2 4	17 04
Bowers, D	370	20	1 20
" "	404	500	30 00

EVERETTE'S MINING OFFICE,

Pioneer Mining Office of the Northwest Coast.

Having the largest permanent brick assay furnaces, chemical laboratory and mining office on the Northwest Coast, with a collection of about 4000 samples of the ores of Alaska, British Columbia, Oregon and the Northwest Territories; and having made personal examinations of nearly every mining camp on the Pacific Slope, from California to Alaska, I am prepared to do any class of legitimate and honest mining work, such as EXAMINING, ENGINEERING, SAMPLING AND REPORTING ON THE VALUE OF ALL MINERAL, COAL AND FIRE-CLAY PROPERTIES, BUILDING STONES, EARTHS, ASSAYS AND ANALYSIS OF ORES, WATERS, CHECK, SAMPLES OF ORE, PULPS, "ORGANIC ANALYSIS" WORK, and in fact any work connected with the office of a first-class mining geologist and chemist. Any information mining men may desire to know relative to the MINERAL OR COAL RESOURCES of the entire Pacific Northwest will be honestly given. Address **Dr. Willis E. Everette.** Consulting Mining Geologist and Chemist, 1318 E Street, Tacoma, Wash.

CERTIFICATE OF PARTNERSHIP.

We certify that we constitute a partnership transacting business in the City and County of San Francisco, State of California, and in this State. Its principal place of business is at San Francisco, California. Its name is CONNOR & GRANT. The full names and respective places of residence of all its members are as follows, and the said copartnership to commence June 1st, 1890.

SAMUEL B. CONNOR, San Francisco, Cal.
ANDREW S. GRANT, San Francisco, Cal.

STATE OF CALIFORNIA, } ss.
City and County of San Francisco. }

On this 12th day of July, in the year one thousand eight hundred and ninety, before me, Geo. T. Knox, a Notary Public in and for the City and County of San Francisco, personally appeared Samuel B. Connor, of said City and County and State, and Andrew S. Grant of the same place, each personally known to me to be the persons whose names are subscribed to, and who executed the within instrument, and they acknowledge to me that they executed the same.

In witness whereof, I have hereunto set my hand, and affixed my Official Seal, at my office, in the City and County of San Francisco, the day and year in this certificate first above written.

[NOTARIAL SEAL.] GEO. T. KNOX, Notary Public.

COLTON DENTAL ASSOCIATION,

Gas Specialists,

Phelan Building, Parlors 6, 7, 8, 9 and 10. Entrance, 806 Market Street.

The only office in this city that makes and gives the celebrated "COLTON GAS," which has a world-wide reputation for its purity and efficacy in the painless extraction of teeth. The large quantity daily used insures the Gas to be always fresh and pure. Over 85,000 references. Recommended and indorsed by all the leading physicians, surgeons and dentists on the coast.

"A RIGID EARTH," being devoted to Geology as Applied to Mining. By STEPHEN BARTON. In this work the author addresses himself to intelligent Miners who have, to some extent at least, familiarized themselves with the accepted theories of elementary geology. He has grouped together numerous observed facts tending to disprove the igneous theory, and to establish the proposition that below the action and influence of the atmosphere all fissures grow narrower with depth—that metal-bearing veins are produced by causes acting near the surface; and that the realm of successful mining never penetrates the earth one mile. PRICE $2.00. J. O. WARD, General Agent, 64 Main Street, Visalia.

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

Day's Improved Quartz Stamp Mill.

This Mill is designed for the Prospector, the Assayer and Sampler of Gold and Silver-bearing rock. It is a perfect mill, built entirely of metals, and of the best mechanical construction; will amalgamate perfectly in the battery or on plates. It strikes a sharp, heavy blow with a light stamp. Shipping weight, 225 lbs. Price $75. Address

JAMES DAY,
ATLAS IRON WORKS, Cor. Napa and Louisiana Streets, Potrero, SAN FRANCISCO, CAL.

N. B.—CHAPPARELL, Butte Co., Cal., Nov 10, 1889.—Mr. Jas. Day, Chico: The little mill is a daisy; it comes up to all expectations; it works perfect in all respects. Yours truly,
WALKER, REESE & CO.

SALT LAKE CITY!

ONE OF THE GREAT FIVE.

New York, Chicago, Denver, Salt Lake City and San Francisco.

Midway between Denver and San Francisco, 700 miles from either, with no rivals north to British Columbia or south to Old Mexico. **Salt Lake City** is destined to become one of the great **Overshadowing Commercial Centers** in the chain between New York and San Francisco.

The **recent mighty inflow of the best American blood** has **doubled** her population, begun the development of **untold resources**, built up **strong churches** of all leading denominations, created **charming social conditions**, fostered the public school system, **directed municipal improvements** and opened the **most profitable Business Investment, Manufacturing and Mining Opportunities ever presented** by a city that in three years will contain **over 100,000 people**, and before the end of the century several times that number.

MORE MINING CAPITAL NEEDED.

The resources of Utah as a mining region may be shown by the following from the books of the **ONTARIO SILVER MINING COMPANY, Park City, Utah** (near Salt Lake City):

Dividend paid, No. 106, to April 1st, 1890. $10,850,000.00; ore and bullion sold to April 1st, 1890, $24,121,203 13. Incorporated January 1st, 1877. Capital Stock, 150,000 shares; par value of stock, $100 00 per share; market price of stock, $45.00 per share and upward. Average number of men employed, 426. Value of improvements and property (inventory December 31st, 1889), $2 985,854.77

The Company pays regular monthly dividends of $75,000.00 or 50 cents per share. Utah has numerous dividend payers on a large scale. There are many other mines that are partly developed that promise the richest returns, with sufficient capital. Within three months, coke from our own home coal (Castle Gate) has supplanted foreign coke in our lead smelters.

Salt Lake City is now one of the most delightful homes in the world, with a perfect climate, good society, churches and schools. 50,000 population and growing rapidly. We will be pleased to correspond with mining men and capitalists and point the way to some specially inviting fields. We have many Mining capitalists here, who will cordially meet and aid new men Our field is large, there is room for all. For illustrated pamphlets, summer tourist rates, and specific information, address

Real Estate Exchange,
SALT LAKE CITY, UTAH.

The Pittsburgh Boiler Scale Resolvent.

☞This Resolvent IS NOT AN EXPERIMENT but a FACT, and it will do the work claimed for it at a LESS EXPENSE than any other boiler purge, AND IN NO MANNER INJURE THE IRON.

CARNEGIE BROTHERS & CO., PROPRIETORS OF EDGAR THOMSON STEEL WORKS, PITTSBURGH, PA. WORKS AT BRADDOCK. Oct. 4, 1887.

We use the Pittsburgh "Boiler Scale Resolvent," and are well satisfied with the results obtained. We have tested nearly all Compounds presented to us, and this one **is the only good thing we have ever used.** Our feed-water is heated in Berryman Heaters, but owing to distance of heaters from boilers, we rarely exceed 150 degrees of heat in feed-water.

Our water is of the worst character, containing such bad impurities as **sulphate of lime, carbonate of lime, mud, and everything that is bad.** Very truly yours, WM. R. JONES, Gen. Supt.

No water in the United States produces scale in greater quantity or of a harder nature than the Monongahela River, containing SULPHATE and CARBONATE of lime, iron, MAGNESIA, SILICATE, SULPHUR, ALUMINUM, etc. The following well-known manufacturers, who are large steam users IN PITTSBURGH, and using the water from said river as boiler-feed for all their boilers, USE THIS RESOLVENT in their steam plant, and to whom reference is hereby made: Carnegie Brothers & Co., Proprietors of the Edgar Thomson Steel Works; Dilworth, Porter & Co.'s Spike Works; and Oliver and Robert's Wire Co.; and many other firms in the great manufacturing center WHERE THE RESOLVENT IS MADE. Reference is also given to Robert McMahon, Boiler Inspector for Alleghany Co., Penn., and to the following Railway Companies who use it on their locomotives: Kansas City, Fort Scott & Gulf Railroad; Central Iowa; Mexican Central; Delaware, Lackawanna & Western; Burlington, Cedar Rapids & Northern, Terre Haute & Indianapolis; Mexican National; and Denver & Rio Grande Western.

Upon receipt of order, WITH THE PROMISE OF FAITHFULLY CARRYING OUT THE PRINTED DIRECTIONS, we will furnish, FOR FIRST INTRODUCTION, a Barrel, or Half Barrel, of the Resolvent, and the invoice will bear the following stamp:

{ TO BE PAID FOR WHEN RESOLVENT PROVES ENTIRELY SATISFACTORY. }

BOISE CITY, CAPITAL OF IDAHO.

Metropolis and by provision of Constitution Permanent Capital. Unusual opportunities for investment and business. Capital needed. Mortgages net 10 per cent. Saw mills, brick kilns, woolen mills, iron works wanted. Unlimited water power. Best society, schools, churches. Perfect climate. Stock growers' paradise. **Free Government Land.** Great grain, fruit and vegetable country. Field crops net $25 per acre. Idaho, "Gem of the Mountains," will soon be a State. Third in precious minerals. Output last year, $17,000,000.00. Combine business with pleasure and visit us. Excursion rates.

IDAHO, "GEM OF THE MOUNTAINS."

Idaho's rapid increase in late years in mineral production is due to the scientific methods formed by capital and long experience. There is large opportunity throughout the mining districts of Idaho to develop mines with almost the certainty of large profits. Gold bullion is cached at the Government assay office in Boise City. At the same time no mining field offers more attractive inducements to the hardy miner whose capital lies chiefly in his experience and in his pick. Full and complete information concerning Idaho mines will be mailed on application.

IRRIGATING CANALS.

Another great opportunity for capital in Idaho is in large irrigation enterprises. Projects are on foot to reclaim several hundred thousand acres, but there is room for many other such projects. Idaho has abundance of water, and the profits of irrigation are large and sure.

The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,
Of Different Strengths as Required.
NOBEL'S EXPLOSIVE GELATINE," which contains **94 per cent of Nitro-Glycerine,** and **GELATINE-DYNAMITE, Stronger than Dynamite** and even Safer in Handling.

JUDSON POWDER IMPROVED.
FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

BANDMANN, NIELSEN & CO.,
CAPS and FUSE for Sale. GENERAL AGENTS, SAN FRANCISCO CAL.

COMMON SENSE PULVERIZER AND CONCENTRATOR.
PATENTED DECEMBER 31, 1889.

This is the most practical machine yet discovered for working Gravel, Cement, Clay, etc. By its use you avoid crushing the rocks, which are washed clean, while at the same time it pulverizes the cement and clay and saves the gold, though fine as flour.

You do away with a long line of sluice-boxes and only use about six inches of water. One hundred tons or more of gravel can be worked every twenty-four hours.

It consists of an iron cylinder about sixteen feet long, set horizontal, in which a shaft filled with projecting teeth or arms set in spiral form is made to revolve from 150 to 250 revolutions per minute. At the discharge end of the cylinder there is a screen, where the coarse rock is thrown out, while the finer material runs into another cylinder, built in the same way, about twelve feet long, the shaft of which is made to revolve double the speed of the first one, thereby breaking up the finer pieces of cement or clay and freeing the gold, which is deposited in the bottom of the cylinder.

Satisfactory recommendations furnished from practical miners who have seen the machine in actual use. Address

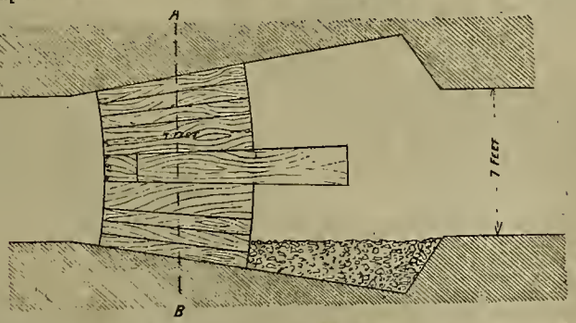
CONDENSING STEAM-PUMPING ENGINE, WITH TRIPLE CYLINDERS.

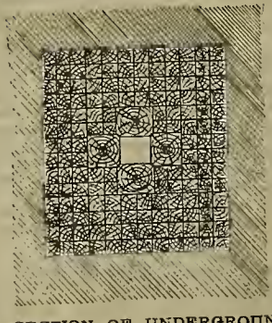
A Triple-Expansion Pumping Engine.

The accompanying cut represents a condensing steam-pumping engine with triple cylinders, 9, 14 and 24 inches in diameter, 24-inch stroke. It was built by the Risdon Iron Works of this city, on the Davidson system, for the town of Jamaica on Long Island, N. Y. The pump is 24 inches in diameter, and the duty 4,000,000 gallons per diem, though it has performed 50 per cent more than that without excessive piston speed. It is the first use of three cylinders with so high a degree of expansion of direct-acting steam pumps. Working at full stroke, the expansion is ten volumes.

The arrangement of three cylinders tandem, with the intermediate and low-pressure ones abutting, as shown, calls for a special arrangement of the piston-rods so as to avoid internal packing. The high-pressure piston at the rear end, or in the front of the drawing, is connected with the piston of the low-pressure engine in the middle. From the piston of the latter there are two rods passing alongside of the intermediate cylinder in tubes, provided with packing glands next the pump in front. These two rods are there keyed into a crosshead on the rod connecting the intermediate and pump pistons, so that the high and low-pressure pistons are on one rod and the intermediate and pump pistons on another, the two sets being connected by the side rods as just explained.



LONGITUDINAL SECTION OF UNDERGROUND DAM.—See page 126.



CROSS SECTION OF UNDERGROUND DAM.

COAL.—The strike of the Wellington miners has made a scarcity of coal in this city, as only 30 of the 900 miners are now at work. The Pacific Improvement Co.'s mine at Carbon Hill is also in some trouble, owing to an injunction served on the company by the Fish Commission for washing the coal in the Colorado river, thereby destroying the fish.

THE FOUNDRIES continue to work steadily along, and although there are more or less desertions of non-union men, others are immediately brought to fill their places. The foundrymen, though put to some inconvenience, have men enough in the molding departments to carry on their usual business.

THE Granite Mountain Mining Co., Montana, paid a dividend of 50 cents per share on the 11th inst., aggregating $200,000, and making a total of $1,600,000 paid this year.

CORRESPONDENCE.

We admit, unindorsed, opinions of correspondents.—EDS.

The Gold Belt of Northern California.

Ancient River Channels and Gravel Deposits.

NUMBER XI—CONCLUDED.

[Written for the MINING AND SCIENTIFIC PRESS by JAMES F. TALBOTT, Blue Canyon, Placer Co.]

Considering the present outlook for hydraulic mining, with all of the favorable indications staring the miner square in the face, and all of the advantages here presented, it is unaccountable that no effort is made to open out drift mines on the deep channel in this ridge.

The great changes in the character of the gravel mines, from the pioneer days to the present time, were so gradual that the point where one class apparently led into the succeeding one was rarely observed at the time.

Classes of Gravel Claims.

There are three distinct classes of gravel mines recognized: First, the bars, rivers, ravine and canyon diggings; second, the deep gravel deposits on the hills; third, the deep channels underlying the lava-capped ridges.

With but few if any exceptions, each class was first discovered by accident, and afterward the discoveries in that class were extended by a comparison with the conditions observed where the deposits of pay were found. The first discovery of gold in California by Marshall was by accident, on a bar on the South Fork of the American river. There was nothing peculiar or different in the conditions of that bar from any other on the South Fork or any other river bar. All of the conditions were observed on the bar where the gold was first found. On comparison, other bars were found to be exactly similar. The natural conclusion was that all river bars in the gold region contained gold, that truth of which was subsequently verified.

There is no account of the first discovery in ravines and canyons. It was no doubt by accident, for in many places in pioneer days the gold lay exposed on the surface in the gulches and ravines, many of which proved to be very rich. From this it was inferred that all ravines and canyons were rich, which proved to be a mistake, as the conditions for pay were not so well known then as now. This class of diggings was the only one known for several years after the first discovery and it was apparent from their character that they would be exhausted in the course of a few years. But before any appreciable effects from this source were felt, the second class of deposits on the hills was discovered in Georgia Hill. The discovery of this class gave promise of a more permanent character than the former and gave an impetus to prospecting that has never been equaled in the State. By a comparison with Georgia Hill the conclusion was jumped at that all gravel hills in the gold region contained rich deposits of gold. The result was the discovery and development of nearly all the hill diggings for 50 miles to the north on this gravel belt and added carloads to the product of gold. Previous to this, however, in a few places rich leads had been followed into the hill and were being worked, but these were considered as local peculiarities and had no general effect like the later discoveries.

Under Lava Ridges.

The third class comprises the channels under the lava ridges. An "accident" occasioned by a big slide on the south side of the ridge near Forest Hill revealed the conditions that led to the first discovery of this class here. By the same course of comparison in this class as in the others the discoveries were extended and the fact established of the existence of mines of a more permanent character than either of the others. The natural conclusion is that all lava-capped ridges of this character within the gold region contain similar mines, the correctness of which appears to be well sustained as far as developments and discoveries have been made up to the present time.

For the past 20 years or more I have entertained the views herein expressed; and following on this line of reasoning, by a comparison of the surface conditions observed on the Shady Run Ridge with those on the Forest Hill Ridge, the similarity is so striking that I believed the underlying conditions would be found to correspond, and that a deep channel could be found in the former similar to the one in the latter, running on the same course from northeast to southwest.

As an earnest of my confidence in the result, about 15 years ago I bought and located mining ground of considerable extent, covering the lava-capped ridge, for the purpose of prospecting, to determine the correctness of my views. I located and started a tunnel with the resolution to see if there was a deep channel underlying the ridge, and if so, to find the bottom of it, if I lived long enough. The undertaking was termed by local mining experts, most of whom were "cross-channel theorists," as "a d——d fool operation," and predicted I would strike high bedrock before getting back 500 feet.

A Practical Example.

For the want of means but little more than the required annual expenditure was done for several years. All efforts to procure any assistance from local capital were unavailing. Persisting in my efforts, I formed the acquaintance of an enterprising party of San Francisco who took a favorable view of the situation and was willing to put some money in the plant. Accordingly an adjoining location was made, and the claims consolidated under the name of the Elite Consolidated Mining Company. Work was then commenced and the tunnel that had been started was extended back into the ridge 1100 feet, from which point a shaft was sunk 158 feet to bedrock. [See engraving of section of ridge and gravel claim on another page of this number of the PRESS.—EDS. PRESS.]

About 600 feet east from the station at Shady Run, at the head of a ravine, where the rimrock has been carried away and exposes the cement to the depth of 50 feet, overlying 5 or 6 feet of fine quartz gravel on the bedrock, the tunnel, six feet wide and six high, starts in the rimrock on a drainage grade and runs on an air line, north 70° west, the distance of 1100 feet. It was known this was not deep enough to bottom the channel, if there proved to be one. The calculation was that the tunnel could be run in the cement at this point and a shaft sunk to ascertain the depth—much cheaper than any other mode of prospecting—and if pay was found the mine could be operated through the present works, which are substantial and constructed with reference to such a contingency, until a tunnel could be run to bottom the channel. From where the present tunnel starts in, the bedrock pitches gradually to the northwest and dips under the cement about 200 feet back. The tunnel passes about 200 feet perpendicular under the railroad right at the station. The cement along in the tunnel here is as hard and solid as ordinary slate bedrock. After passing some distance beyond the railroad to the west, strata of coarse sand were encountered. Occasionally the whole face of the tunnel would be in a bed of sand. On this account 400 feet of the back portion of the tunnel was substantially timbered. When coming into a solid body of the cement again, the shaft was started. At the depth of 35 feet the cement gave out, and 20 successive distinct strata of sand, gravel, clay and lignite were passed through before bedrock was reached. At the depth of 52 feet we came on to a stratum of solid, compact white clay. Immediately underlying this was found an unmixed bed of lignite three feet thick, composed apparently of a drift of wood, bark, leaves, grass and other vegetation, among which cedar bark and tamarack wood are readily distinguished. One of the curiosities found here might be of interest to the naturalist—that is, on the leaves of what appears to have been some kind of a water plant is found a small insect of a bright green color as natural as life. In size and color it resembles very much a small insect often seen skipping along on the surface of still water in streams or clay with lignite in thin layers intermixed all through.

At the depth of 100 feet we passed through a bed of pipeclay 22 feet thick. Below this was a few feet of sand and drift. The next below was as fine a body of smooth washed quartz gravel and cobble as I ever saw; and here the first color of gold was found 1100 feet back from the outside rim and about 500 feet from the surface on the ridge. In every pan of this gravel, fine colors of gold can be got. Where the gravel was struck in the shaft, it dipped to the northwest into the ridge at about 15 degrees, while the bedrock 25 feet below pitched in the same direction on an angle of 35 degrees, which induces the belief that this is the lower rim of the deep channel. When it is considered that the rimrock along on Canyon creek is about on the same level with the C. P. R. R., that this tunnel runs about one-fifth the distance through the ridge toward that rim, and that the bedrock pitching steep in that direction at the end of the tunnel is 350 feet below the railroad track, the fact is established beyond a doubt of the existence of a deep channel, which fact is *now* generally admitted.

Admitting the existence of the channel, the pull now is, you don't know if there is any pay in it.

Pay in Deep Channels.

The indications are as favorable and the presumptive evidence as strong in regard to the pay as to the existence of the channel; and it is the present intention of our company to demonstrate the former in as positive a manner as we have the latter, by running a slope from the end of our tunnel on a grade that will reach the bedrock 300 feet beyond the shaft, where it is confidently believed we will strike the original deposit of gold in the deep channel of the North Fork Divide, that will develop as rich as any found in the Gold Belt. The fact of the two ridges that form this divide uniting, as heretofore described, evidently shows their contents were derived from the same source. Upon reliable authority, the figures show that $100,000,000 of the contents of this divide have been realized in the output of gold since 1849, from the gravel mines alone, between the South Yuba and the North Fork of the American, the greater portion of which came from the Nevada Ridge. Owing to the peculiarity of that ridge in spreading out over a wide extent of country that was easily prospected, many of the rich mines were developed at small expense, which attracted the capital that subsequently developed the vast mineral resources of that section.

Shady Run Ridge.

The peculiarities of the Shady Run Ridge are its narrow, confined condition, with but few gravel deposits connected with it. In regard to its contents, nothing directly is known, but from all of the surrounding conditions, the natural inference is that it contains rich deposits of gold. It is situated right in the center of the Gold Belt, with rich drift mines both on the north and the south, and for 15 miles or more on either side the ridge, where the rim has been cut away to a certain depth, rich spots of pay have been found in the near vicinity and nowhere else. The millions of dollars in fine gold taken from the Dutch Flat and Gold Run mines unmistakably came principally from this ridge. With all of the favorable indications and advantages presented, with the exception of a few individuals gouging around in outside spots, there is not a drift mine between Bear river and the North Fork of the American. Why is this so? Simply because the drift mines of permanent value are buried deep beneath the lava-capped ridge, beyond the reach of the individual prospector's means, and companies with capital decline to take hold until something rich is developed.

Future Drift Mines.

The fact is now pretty well established that the future drift mines of permanent value will have to be sought for under the deep lava-capped ridges that overlie the ancient channels, and from a careful observation of the surface conditions and following on the line of natural methods here indicated, it is confidently believed that every ancient channel on the western slope of the Sierras within the Gold Belt can be as definitely traced out as those of the Middle and North Fork of the American.

Causes of Failures.

There are few localities in the mining region but what have been cursed with some bogus prospecting and mining operation managed by a class of "pedro" miners more for the purpose of the five or ten dollar a day salary than to obtain valuable results. The method is to make a haphazard location of a claim as near the town as circumstances will permit, or bargain with a silent partner for a worked-out claim at a round price. A forced and unnatural connection is made between the claim and every rich mine within the circumference of 40 miles. Some rich friend is taken into the secret of this hidden wealth and supplies the means to obtain it. After spending a few thousand dollars and getting nothing but favorable reports, the rich friend gets a "clue" and takes in the situation, curses the claim, the management and the whole section of country, and permanently retires from the business. Any other kind of business in the country besides mining, based and conducted on this principle, would result in failure. The principle of home rule will have to be adopted, so that each locality will have to stand on its own merits of [illegible] dom find many serious obstacles to overcome in their efforts to run every rich channel in the country through their claims. I would suggest a less difficult method, one with greater possibilities of valuable results—that is, to trace out the channels first, then make the location with reference to them. "In the days of old" all that was required to prospect and develop a rich mine was a mule-load of grub, a pick and pan. The changed conditions now demand considerable money, abundance of muscle and the power of steam. Where these are directed by honest, intelligent, practical miners, on sound business principles, the business of mining will be as successful as any other business in the country.

The "Blue Bucket" Mine.

In 1845, a party of immigrants under the leadership of Stephen Meeks, left the usually traveled route at the month of the Malheur river and traveled up that stream, intending to cross the Cascade mountains at the head of the Willamette valley. Cloudy and foggy weather set in obscuring the land-marks and the party got lost and wandered about the great basin in which Harney lake is situated, for some weeks, suffering intensely for food and water. During this wandering some one brought into camp some substance supposed to be gold dust. Out of this find has grown the mythical mine, sometimes called the Wagon Tire mine and sometimes the Blue Bucket mine. The term "Wagon Tire" was applied, because it is said in testing the substance, some of it was beaten flat on a wagon tire, from which circumstance it was concluded the substance was gold. When it was concluded that the yellow stuff was gold, one of the enthusiastic finders exclaimed: "Why! if that is gold, I can fill a mine bucket with it;" and from this expression it is sometimes called the Blue Bucket mine. The parties were too much pressed with hunger and thirst to stop and locate the mine. It must also be borne in mind that all this occurred in 1845, prior to the discovery of gold on this coast, and at that day people were not familiar with gold, either as dust or coin. From that day until this, wild tales of these mystical mines have been told, and many have been the expeditions which have been fitted out to refind this mine. In a Pendleton paper we see it announced that a few days ago a party started out sanguine of finding the mine.—*Oregon Courier.*

DURING the first seven months of the current year, the Daly mine of Utah had an output of 6316.16 ounces bullion, $295,110.70 of sulphides, and sales of ore which realized $78,273.90. Seven regular monthly dividends, of 25 cents per share each, making a total of $1.75 per share, were paid. The total dividends paid by the Daly to date are $1,575,000.

San Bernardino County.

Its Mineral and Other Resources.

NUMBER VII.

[Written for the PRESS by JAMES H. CROSSMAN.]

Sources of Water Supply.

There are only two important rivers flowing through San Bernardino county on the southerly and westerly slope of the San Bernardino range of mountains, and these are not navigable streams but very important sources of supply for irrigation purposes. The rivers referred to are the Santa Ana and the San Jacinto. There are, however, several large creeks, namely, Mill, Lythe, Warren and City creeks, from which immense quantities of water are taken for irrigating the rich but arid lands of the valley. The other streams that derive their supply from the San Bernardino mountains are the San Louis and San Diego, which, after flowing through and enriching the thirsty soil, discharge their waters into the Pacific ocean.

The desert region north of the San Bernardino range of mountains contains but few running streams. The principal, and in fact the only one of importance and note, is the

Mojave River.

It takes its rise in the San Bernardino range of mountains. Its principal fork is in Holcomb valley and flows northerly for a distance in an air-line of 75 miles from this point. It diverges and takes an easterly course, disappearing and sinking in Soda lake. From this point its waters flow in all probability through subterranean channels and discharge into the Pacific ocean either directly or via the Gulf of California. Its total length as a surface stream is about 200 miles, but it is eccentric to that extent that it is known as "The Hide and Seek River" of the Western continent. During the winter or flood season it forms a torrential stream of considerable capacity, in places overflowing large areas—in fact at this season of the year it carries such a volume of water that the late General John C. Fremont, in the employ of the United States Government in 1846 and 1847, reported to his superior in Washington that it was an inland navigable river (vide Congressional Reports). At its lowest stage in the summer season it carries a volume of not less than 10,000 inches miners' measurement. Its eccentricity consists in appearing and disappearing from view as a surface stream for considerable distances. On its course it disappears from sight several times, either absorbed by the sands, which have the carrying capacity of 22 per cent of water, as has repeatedly been proved by instrumental tests, or flowing through subterranean channels.

It flows as a surface stream from its source to a point 12 miles above Victor, when it sinks and continues invisible for a distance of 12 miles. At this point it comes to the surface, the granitic formation at "the gate" forming a bar to its further subterranean progress. Here it runs for a short distance forming a stream of that magnitude that it is unfordable during the flood season. Disappearing below the surface again, it is not seen for a distance of five miles. At a point above Oro Grande it reappears, having apparently lost none of its volume. Running for five miles, it reappears at a point above Cottonwood Station, and runs for one mile, then sinks and is invisible for a distance of 15 miles, rising at Barstow, where it is only seen for half a mile and disappears for six miles, coming to the surface at Fish Ponds, the site of the Silver Valley Land and Water Company's submerged dam to which I have previously made reference. From this point the water flows on the surface for a distance of one mile, sinks, and is not seen again until it reaches Hawley's Station, 12 miles distant, and flows here for half a mile and is not seen again until it reaches Camp Cady, where it comes to the surface and flows for one mile, then disappears from sight for 18 miles, rising at Cave Canyon. At this point a high ridge and narrow gorge occur similar to that at the "Victor gate" (this rim at one time evidently formed the rimrock of an extensive lake, the ridge standing at an elevation of 300 feet above the river-bed and only 200 feet in width). A dam could easily and cheaply be constructed here, forming a storage reservoir of great capacity overflowing a large area. Through this obstruction the Mojave river has cut its way.

The river now flows uninterruptedly as a surface stream for 10 miles with to all appearances its original volume, until it closes its career (except in extraordinary flood seasons) as a living stream by taking its final plunge into the desiccated and alkaline bed of Soda Lake. At periods of uncommon floods it rises to the surface at a point 20 miles distant and forms a junction with the Amargosa river; the united streams finally lose their waters in the south of Death Valley basin at a point near Saratoga Springs. Where the Mojave river comes to the surface the banks are covered by a dense growth of cottonwood and willow, and when cultivated produce large crops of grain, vegetables, fruit and alfalfa, evidences of the fertility of the soil.

The Amargosa River.

Though of minor importance in its volume and purity, its water being unfit for either agricultural or drinking purposes, this river has an important duty to perform. Its extreme length is 140 miles, commanding an extensive area of

tributary watershed. This river with its affluents courses through a section of the country in which the rocky formation contains an unusually large percentage of alkaline and saline mineral. The erosive action of the waters of the river and its tributaries on these friable and easily disintegrated rocks, with the assistance of atmospheric influences, rapidly destroys their integrity and dissolves the soluble minerals. The pure water of the river, under the powerful rays of the sun in this desiccated region, is segregated and evaporated, leaving the mineral product held in the form of a dense briny caustic solution; as the water decreases in volume evaporation is more rapid and the water becomes charged to its fullest capacity. To the eye of the thirsty traveler it is limpid and pure, but sure and certain death to the man or beast that partakes of it at this stage without remedial measures.

Death valley. From this creek the extensive refining works formerly belonging to W. P. Coleman obtain their supply of pure, fresh water for domestic and other purposes.

Springs.

In the desert region springs of considerable volume and strength occur, particularly in the vicinity of mountain ranges. Their sites were sedulously guarded and concealed from the white man's gaze by the aborigines of the desert—the Pinte Indians. To them they were the key to the citadel. Without water neither white nor red man could exist, and the springs were "few and far between." Drives of from 30 to 50 miles had to be made over burning sands to reach them, and if the traveler without trail or road missed his course and got lost, death was his portion. The Indians held them in greater esteem than silver or gold, but were induced to

side of Death valley at the base of Tom Wattles mountain and 18 miles west of the mouth of the Amargosa river, Tp. 22 N., R. 2 E., S. B. M.

Soda Lake, a dry lake, is situated in Tp. 12 N., R. 8 E. Though a dry lake, it has numerous springs of living water on its borders.

Paradise Springs, situated on the first range of mountains north of the Calico range, 20 miles north of Daggett, at an elevation of 2500 feet, Tp. 12 N., R. 1 E., S. B. M. These springs comprise a group, some of them hot, others cold, water pure.

Garlic Springs are situated on the Resting Spring road, Tp. 14 N., R. 3 E., S. B. M., where, for a distance of four miles, there occur numerous springs, the largest furnishing 18 inches of water, M. M.

Hot Springs lie on the east side of the Amargosa river, near McLane's ranch; temperature

At Chinese ranch on Clark's fork, six feet under the surface, water can be developed in sufficient quantities to run a smelting plant of any capacity.

New York mountain is well supplied with water from springs.

Pahrump valley, at an elevation of 3000 feet, 40 and 18 miles, in extent contains two springs 50 feet apart, the combined flow being 100 miners' inches.

Pahrump spring furnishes a regular flow of 800 inches miners' measurement.

29 Palms.

An important spring occurs in the vicinity of 29 Palms, from which flows a strong body of water. It gushes forth from the foot of a low mountain with considerable force. Its volume is sufficient to form quite a stream which flows for a distance of three miles and sinks in the

HEADGATE AND WASTEGATE OF KERN ISLAND CANAL, TAKING WATER FROM KERN RIVER.

The river has here performed its mission; it has served in a threefold capacity—first, as a disintegrator, second, as a carrier, and third, as a concentrator. Its remaining water is now drank up by the thirsty sands of the desert, leaving its mineral contents on the surface in a crystalline form ready for man's use. The alkaline, saline and borate beds in the region of Death Valley receive their supply from this and other sources, and so long as the sun shines and water runs this and similar regions will continue to produce their quota of these alkaline minerals.

The Amargosa river has its source in the State of Nevada about 30 miles easterly from the State Line gold mine on Gold mountain, and makes its first appearance as a river at the northerly end of the Oasis in Nye county, Nevada. Its general course is southerly until after passing through the Amargosa borax fields near Resting Springs through a deep canyon in the vicinity of the Salt Spring gold mine, where its course suddenly changes to almost due north, when it soon after sinks and disappears at a point near Saratoga Springs.

Furnace Creek

Takes its rise on the western slope of the southerly end of Grapevine Mountain in the Death Valley or Funeral Range of mountains, receiving its supply of about 200 miners' inches of water from a spring of pure cold water. It runs in a westerly direction for a distance of about three miles and sinks in the sands of

impart the secret of their hiding-place to a white man in whom they implicitly trusted by the name of John Mose. He in turn disclosed their whereabouts to members of his race, the prospectors and miners.

To the poor Indian of the Piute tribe is nearly extinct and the well-traveled trails of the white man have replaced the faint moccasin tracks made by the red man's feet. The desert is no longer a sealed book, but can be traveled with comparative safety at least in beaten tracks.

The forthcoming map, to which I have previously referred, will show the principal springs, and this serial article will serve as a text-book that will assist the desert traveler to find them.

Coyote Holes Spring is situated seven miles north of Hawley's station, on the southerly border of a dry lake; water saline and containing two per cent salt and one per cent borax, unfit for drinking purposes. It is in Tp. 11 N., R. 3 E., S. B. M. Thirty miles north of Daggett and on the western border of a dry lake is a spring in Tp. 14 N., R. 3 E., S. B. M.

Irawatz mountain, situated 70 miles northeast of Daggett, on south border of Death valley, contains numerous springs.

Cave Springs are 30 miles northwest of Garlic Springs, in a low gap in the Irawatz range, on the Resting wagon-road, two miles below the summit, on the north side, 13 miles from Tp. 9 N., R. 14 E., S. B. M.

Saratoga Springs are situated on the north

of water, 120° Fahr. It flows 337 miner's inches, and is celebrated for its medicinal qualities—severe chronic cases of inflammatory rheumatism have received permanent cures in brief periods.

Situated in the same vicinity flows thermal water of medicinal qualities, said to be a specific for certain diseases. There is also a cold spring in the vicinity flowing pure and drinkable water.

Oasis Springs form a marshy meadow of eight miles in length by one-fourth of a mile in width.

Ash meadows lie two miles east of the Amargosa river, on the Nevada State line, in which are several living springs of water.

The "Four Springs" occur in the range of mountains that extend along the eastern slope of the Death Valley basin at the base on the west of the range, distant from each other from one to three miles, one of them flowing from 250 to 400 inches of water, miner's measurement, and innumerable small ones that flow from one to 50 inches each. On the south end of the valley is a large spring the water so clear that at a depth of 70 feet small objects can be distinguished on its bottom.

Keane spring is one of considerable strength, 40 miles northeast of Ash Meadows.

Resting springs consists of six springs, flowing from 1 to 100 inches each, situated three miles east of the Amargosa river on the west slope of the Resting Spring range. Tp. 21 N. R. 8 E., S. B. M., 90 miles northeast of Daggett.

sands of the desert. This location is peculiarly adapted for a storage reservoir of great capacity.

The Head Works of a Kern County Canal.

Our engraving shows important parts of one of the leading irrigating canals of Kern county, and gives the distant reader a little idea of the work undertaken to make the waters of our streams available for pushing the large crops annually secured from irrigated lands.

This canal appropriates 20,000 inches of water, equivalent to 400 cubic feet per second. Its location dates back to 1870.

The headgate and wastegate of this canal are the main features in the engraving. The former was built in 1878, and its construction required 75,000 feet of lumber. It is shown on the left of the engraving, and the wastegate is on the right; both are 50 feet in width. The wastegate is made to open from the bottom with chains, in order to flush the sand away from the headgate, which admits the water to the canal. The water through the wastegate goes back into the river. The water is brought to the headgate by means of a wingdam, shown in the foreground of the picture, and the amount taken into the canal is regulated, of course, by the raising or lowering of the wastegate. The water goes into the canal over the gate boards, thus preventing the sand from entering the canal.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

NEW YORK MINE. — *Ledger*, Aug. 16: W. G. Andersnn of the New York mine, about 3½ miles southwest of Jackson, ioforms us that arrangements have been made for the erection of a 20-stamp mill on that claim, the contract for which has been let to the Hendy Works, San Francisco.

SUTTER CREEK.—Cor. Amador *Ledger*, Aug. 16: Improvements at the Wildman mine continue to be made. Since my last reference to this property, three circular saws have been added to the plaot—one for a crosscut, one for tenants and the third for making wedges. Each saw is run by an independent wheel of Knight & Co.'s patent, and these wheels are so perfectly bnxed that not a drop of water is seen to escape. In close proximity to the saw, a powerful derrick has beeo erected to facilitate the handling of heavy timbers, the capacity of which is one ton. A boom is attached, 50 feet long, commanding a space of 125 feet, which is also operated by water-power. This is used for piling logs to a hight of 20 feet if necessary, taking them off the loaded wagons and swinging them into place and to the crosscut saw as needed. This additional machinery alone, according to Mr. Tregloan's estimate, is a saving of the labor of ten men, and the outlay involved was about $1000. Grading for the additional ten stamps to the Wildman mill will be commenced in a few days. Knight & Co. are making 4000 feet of 15-inch douhle-riveted steel pipe to ruo the mill independently of the hoisting works, instead of runniog hoth by one pipe as heretofore. Sinking the shaft is progressing very favorably, averaging oine feet per week, besides doiog some repairiog in the shaft, and the eotire mill is kept running steadily. The Lincoln mill has been hung up for about two weeks, but was again started this week. The ledge is uncovered sufficiently to enable them to run for some time. Operations at the Rose mine came to a sudden standstill last week on account of coming in contact with bad air. Everything will remain idle until air-pipes can he put in. Sinking at the North Star is well-nigh completed, only 30 feet more remaining to complete the work. In two weeks more everything will he in readiness for drifting, and probably two drifts will be run at once, one east and the other west.

El Dorado.

NEW STAMPS.—*Mountain Democrat*, Aug. 16: The five new stamps on the Gentle Annie mine, on Poverty Poiot, have been put in operatioo, and now ten stamps are pounding away on good rock from the claim. A new tunoel has been started on the north end of the mine, and a new track laid from that point to the mill. An increased force is now at work, and the mine is booming aloog in a manner very satisfactory to the owners.

Fresno.

MINARET IRON MINES. — Fresno *Republican*, Aug. 15: P. B. Donahoo, Peter Hanson, John Hanson, W. S. Nelson, J. Robinson, M. Deneke and C. Beck have returoed from a trip to the Minaret iron mines, which they visited for the purpose of determining the exteot of the deposit. The ledge stands up in one place as a perpeodicular wall 1500 feet high and extends along the mountains for a distance of between one and two miles, having ao average width of 300 feet. The ore is as rich as that of the richest iron mines in the world, assaying 67 per eent of iron. It will make a fine quality of steel, but owing to a trifling excess of phosphorus it cannot be used for Bessemer iron. There is an abundance of water-power near the mine and also of wood for fuel, and smelting works could he maintained there at comparatively small expense. But it cannot he developed without a railroad conoecting it with Fresoo. The gentlemen interested in the mines say that a railroad can be constructed with an easy grade along the San Joaquin river to its headwaters without getting into the snow helt.

Inyo.

THE SALE MADE.—*Register*, Aug. 14: Messrs. Turner and Sanboro, the purchasers of the Kincaid mines at Sylvania, and W. F. Kincaid were in town this morniog. While here they acknowledged, before Notary Forhes, the fioal deed to the mines upon which, to a large extent, depend local hopes. The purchase-money, $15,000, bas heen paid over, and Messrs. Turner, Sanborn and Fife now enter into full possession of the Sylvania property. This means that the mines will be developed if coin will do it. The ore, by the way, is improving in quality with the depth of the shaft.

FISH SPRINGS.—*Register*, Aug. 14: From Henry Melone we learn that the Fish Spriogs mines, five miles south of Big Pine, are paying. The Melone & Fuller mine, koown as the Yellow Gnat, is getting into shape to pay more than expenses. The shaft is down 100 feet. From the bottom two drifts are run, one 40, the other 50 feet. A tunoel, 140 feet, cuts the ledge 225 feet from the surface, therefore, 125 feet below the bottom of the shaft. Last week seven tons of ore were run through the arastra and yielded $53 per ton. The tailings were afterward sold for $5 a 100, so the ore is of first-rate quality.

AN OLD CLAIM.—Tradition, at least, says that 25 or 30 years ago an old Freochman mined well and successfully at some point across here to the eastward in the White mountains. With a small arastra he got out enough gold to carry him back to Fraoce. In this view he told his countrymen of his mine, upon which a company was orgaoized and a party sent here to find and work it. In the meantime the big earthquake of '72 had beeo here and so banged things around in that vicioity as to cover up every trace of the old workings, and the party gave up the search and went home. And now comes Nathaniel Williams, who has been working over here in the Inyos, aod says that he has at last found the workings, though they were covered up by the earthquake. If the claim paid so well in those days, it ought to prove a big bonanza in these days.

REDDING CANYON.—Messrs. Hill, Anderson & Williams, owners of the Enterprise and Georgia mines io Redding canyon, have let a contract to Geo. F. Willis to run a 30-foot drift in the Enterprise. These prospects are likely to become paying and valuahle properties, assays and indications all favoring the existence of a big ledge in the immediate vicinity. Water and wood are at hand, the former in quantity sufficient to run a small mill or arastra The mines are half-way up to the summit of the White Mountains, four or five miles from the railroad track and eight or nine miles from town.

Mono.

BODIE.—*Alta*, Aug. 21: The west crosscut from top of upraise from south drift, 700 level, was extended 5 feet. North drift from joint crosscut, 700 level, was extended 13 feet. East crosscut from main north drift, 700 level, was extended 6 feet. West crosscut from same drift was extended 24 feet.

MONO.—The south drift from joint crosscut, 700 level, was extended 8 feet.

BULWER.—The south drift from No. 1 west crosscut, 400 level, was extended 27 feet. Started upraise from same drift and extended it 12 feet. Upraise from south drift, Bulwer tunnel level, was extended 5 feet.

Monterey.

LOS BURROS DISTRICT.—Salinas *Democrat*, Aug. 6: Joseph McArthur of Mansfield, Los Burros, stopped over in Salinas Tuesday on his way home from San Francisco, where he had been for a few weeks forming a company to operate a copper mine in the Los Burros district, this county, in which work he succeeded. The mine will be opened immediately uoon his return, and all the necessary tools, powder, etc., have been shipped by rail to King City, from which point it will be traosported to the mine. The ledge has already been prospected to a depth of 30 feet, at which point it is 40 feet wide. From an assay of ore taken to the city, it showed pure copper from 12 to 45 per cent, $6 in gold and 4 ounces of silver to the ton. The location of the mine is about 8 miles south of Mansfield aod about 1½ miles east of the Pacific ocean. Pure copper has a commercial value of 17 to 18 cents per pound, and at 12 cents per pound the product of this mine with a 10-ton smelter would produce 4500 pounds io 24 hours of a total value of $540, netting the company $415 per day. We are also informed by Mr. McArthur that Wm. Cruikshank has discovered a very rich quicksilver ledge, about 4½ miles south of Mansfield and two miles from the ocean. The ledge is between three and four feet wide on top and is very rich in quicksilver. A tunnel is now io 125 feet, and it is expected that the ledge will be tapped at 150 feet. Mr. McArthur is also the discoverer of a manganese deposit from which 40 toos have heeo taken and are now on the dump. The deposit ranges on the surface from 4 to 10 feet wide, and over 150 toos are cropping out. The product of this deposit is pronounced as of the finest quality. The Grizzly mine in Los Burros has recently made its second shipment, within six weeks, to San Francisco, the amount being $2000. As the water has given out, arrangements have been made by this company to mill its ore at the Cruikshank works.

Nevada.

WILL MAKE A MINE.—*Tidings*, Aug. 16: For three months past the W. Y. O. D. mine has been paying its way, although sinking and drifting have been steadily pushed aod but little stoping done. The ledge in the drifts at the 600-foot level is of good size, showing gold and considerable sulphurets, and the country ground is favorable. In the shaft which is being put down for the 700-foot level, the vein is as strong and of as good quality as in the drifts, affording every indication of permanency. The force of miners is to be considerahly increased shortly, when the stockholders may expect to receive the reward so richly merited by reasoo of the confidence aod persistence shown. The management is highly elated over the outlook. The annual meeting was held Friday evening and the followiog stockholders elected directors for the eosuing year: E. J. Brockington, president; W. J. Connors, vice-president; Joseph Weissbein, secretary; Jacob Weissbein, treasurer; and C. A. Brockington. The last-oamed gentleman was re-elected superintendent.

A RICH BOWLDER.—Grass Valley *Union*, Aug. 17: A few days ago, while workiog in his gravel claim at Dutch Flat, Jeff Doolittle found a bowlder of quartz character, heavily laden with gold. The bowlder weighed 11 tons and has been hrokeo up, and for the past few days teams have been eugaged in hauling it to Nevada City where it has been put through mill process. The yield is about $150 per ton. How many more of just such pieces are lying around in all our gravel mines.

THE COE MINE.—Grass Valley *Union*, Aug. 18: Arrangements have been fully made to open up and work the Coe mine. The Grass Valley Queeo Gold Mining Co., an incorporation, has undertaken to work on the Coe, and the same incorporation will probably work other mines in this district. The work of pumping out the Coe will begio to-morrow, under the foremanship of James Hammill, ooe of our most experienced miners, and a mao of the best kind of hard practical mioing sense. Mr. Robert Stevenson represents the Grass Valley Queen Co.

HOLBROOKE AND HARRINGTON GRAVEL MINE Grass Valley *Union*, Aug. 18: This is the name by which the Webster gravel mine at Randolph Flat is now known and upoo which work has been resumed after the mine has lain idle since the year 1871. The enterprise is heing conducted by Mrs. E. E. Holbrooke of this place, who, satisfied of the value of the ground, which produced over $50,000 duriog the former working, decided some months ago to put up steam hoisting works aod sink a new incline shaft on the gravel channel some distance from the old shaft. Ground was hroken on the new location on the 20th of July, and since that date a road has been constructed to the site, a boarding-house for the workmen built, a hoisting and pumping works erected, and the incline sunk to. a depth of 45 feet. The hoisting works are 36 by 70 feet in dimeosions, and 20 feet in hight, the secood story being used as the landing floor for the cars. The engioe is a 9½-inch cylinder with 12-inch stroke, aod all the hoisting and pumping gear is compact and strong, and all the woodwork about the machinery is solid and substantial. The incline shaft that is beiog sunk is 8 feet by 5 feet 4 inches, with two compartments—one for pumping, the other for hoisting. Night and day shifts are engaged in sinking the incline, which near the surface is through cemented ground mixed with bowlders and gravel. The shaft is on an inclination of 75 degrees and will be in vertical depth 120 feet, or on the incline 170 feet to the bottom of the channel, which is ascertained from the former workings. The shaft is now being sunk and timbered at the rate of five feet per day. Mrs. Holbrooke deserves great credit for her energy and pluck in opening up the mine after it has been so long idle, and from all reports it looks as though she would meet with the reward she deserves.

Placer.

THE KIRKLAND MINE.—*Herald*, Aug. 16: The German company that recently bonded the Kirkland mine near Ophir—an extension of the now famous Hathaway—are working eight men in sinking on the ledge with the view of better developing its character. They are now down about 150 feet, and at the bottom of the shaft the ledge is about three feet thick and the character of the ore is very favorable. Fraok Brannon, late of Alaska, is superiotending the work.

Plumas.

THE ALTOONA MINE.—Greenville *Bulletin*, Aug. 17: Early in the week, in company with the owoer, we had the pleasure of visiting this mine. It is located near the top of the mountain above the Green Mountain mining property, of which it appears to be a continuation. Judge Emmons has owoed it several years, but had not the means to develop the property. Last year, however, he pushed a tuonel in on a large vein of quartz, which he took out aod crushed, hauling it a long distance to a mill for that purpose. The returns were satisfactory. Two miners—Mr. Cavanaugh aod Mr. Potts—are now at work driving the tunnel ahead. In the face of the drift the vein of quartz is eight feet wide. It is fine-looking and prospects well. This development is of much importance. It can be reached at great depth quite easily through the Green Mountain tunoel, and through it could be mined and milled very cheaply. The ledge is betweeo well-defined walls standing at an angle of about 45 degrees.

Shasta.

OLD DIGGINGS DISTRICT.—Cor. Redding *Free Press*, Aug. 16: Messrs. Whitehouse and Bliss of New York have decided to develop the Central mine at once and will go to work as soon as arrangements can be perfected. Mr. Champion bought another large mine—the Trinity, on Dog creek. He expects to go to work soon and develop one of the finest properties in the State. Walker Bros. made a good cleanup on the 1st inst, and shipped a carload of concentrates to the Butters Ore Milling Works at Kennet the same day. Hart & Fleming shipped a carload to the Selby Smelting Works Aug. 9th. Twenty-two mining men, experts and capitalists, in Redding one day last week. Mr. Hart has gone to San Francisco to "railroad" a U. S. patent through for the Texas and Georgia mines. A sale of this valuable property to the Sierra Buttes Co. is practically complete. We uoderstand that a price has been agreed upon and all that is needed is a title; the purchasers being aliens cannot get a U. S. patent. This shows the importance of securing patents for mining claims. It appears that the big scheme spoken of by the *Free Press* is about to materialize.

MINES PURCHASED.—Redding *Free Press*, Aug. 16: On the 9th inst. the Gladstone group of mines was purchased by the Bimetallic Mining Company of Montana. We are not informed of the purchase price. It is encouraging to the French Gulch people to go ahead developing mines, when a solid and successful company like the Bimetallic comes in and pays a big cash sum with much preliminary examination of the property. These mines are said to be an exception, having beeo dividend payers under the adverse circumstances of having a patent quartz-mill to work the ore instead of a standard battery.

Sierra.

PIKE CITY.—*Mountain Messenger*, Aug. 6: We are informed by J. H. Ryan of Pike City that there is a good prospect of a big boom in mining at that town, average ore yielding $12.84 a ton from the surface vein, having been taken out of the Grizzly ledge opposite the Alaska quartz-mill. The property is owned by Miles I'Ansen of Newark, N. J. Mioing capitalists from San Francisco are coming to Pike City to look at the merits of the Alaska quartz ledge, having failed to find a mioe that suited them in Grass Valley.

THE SIERRA BUTTES MINE.—Sierra *Tribune*, Aug. 16: The Grass Valley *Tidings* is wrong in stating that the Sierra Buttes is to be dismantled or, in other words, abandoned. It is too late in the season to do much now, but next year the 20-stamp mill at No. 7 will be rehuilt and it will be erected io a place where snowslides will not be likely to reach it. In addition to taking out ore enough to keep the mill going, there will be prospecting going on, and perhaps the future history of this mine will figure something after the Plumas Eureka, which mine, our readers will remember, went dowo to a very low ebb a few years ago. In fact, operations were about to he suspended there, but a little further prospecting was done, a new body of ore was opened up and the mine to-day is paying handsome dividends. The Sierra Buttes is a big mountain and the mine named after it has heen a big institution, too, but there is no reason to suppose that the great hill has yet delivered up all its riches.

A BIG MINING ENTERPRISE.—Three miles southwest from the Mountain House the Golden Giant drift mining company is operating. They have run a tunnel 1200 feet into the mountain aod are now engaged in putting in a Burleigh drill. As soon as the drill is got in working order the tunnel will he pushed ahead to the channel, which, it is figured upon, will be reached in 600 feet farther. The drill machioery was purchased from A. C. Busch of this place, who is also one of the owners in this enterprise. John Gale of the Mountain House and several Downieville parties compose the balance of the company.

THE MOUNTAIN MINE.—The road leading up to the Mountaio mine, for which Hagerty & Flint have the contract to build, will be completed inside of three or four days. Work on the tramway is beiog pushed ahead as rapidly as possible and the contractor expects to have it running in three or four weeks. The mill is covered and the battery blocks are being placed in position. The mill will be ready to start up by the time the tramway is completed.

THE ORDER OF THINGS REVERSED.—The ore coming out of the stope on the west drift of the No. 17 level of the North Star mine at Grass Valley cootinues to be of extraordinary richness. Some newspaper down there said that the floor of the office was literally paved with gold. That reverses the order of things. Generally the gold is used to line the pockets of the office-holders.

ADDITIONAL STAMPS.—Three additional stamps have heen ordered from the Downieville foundry for the mill at the Wm. Tell mine. The present three stamps are pounding away regularly and the plates are showing up in fine shape. Mark the *Tribune's* prophecy: The Wm. Tell is going to develop into one of the big mines of California.

A GOOD PROSPECT.—Up at the Mexican ledge, located above the Wm. Tell mine and owned by Tony Grass and Caspar Joos, a shaft is being sunk, and lately a good-looking vein of four or five feet in width was encountered. That seems to he a good neighhorhnod for quartz ledges.

PROSPECTING.—A. L. Moore aod Messrs. Taylor & Thomas, the surveyors, are running a tunnel on their quartz ledge near the Phœnix mine.

San Diego.

AT BANNER.—Julian *Sentinel*, Aug. 16: J. R. Pollard was up from the Banner the first of the week. He informs us that he has obtained a third interest in the "76" mine and will go to wnrk on it at once.

Tuolumne.

PLATT & GILSON.—Tuolumne *Independent*, Aug. 16: Mr. C. Hermann of San Francisco has been in town the past week paying off the iodebtedness of the Platt & Gilson mine, of which Mr. H. is the principal owner. We understand that the mine is now unincumhered, and that operatioos have been commenced. Supt. Tritenhach has resumed charge. We are informed that the old company has been disbanded, a new company formed, and the stock divided into 30 shares.

MINING SUIT.—The McCormick Bros. have commenced a suit against the Sanguissipi Mining Co. Accordiog to the survey lines, they claim the mine is on their ground. The mill has been shut down, but the contractors are still sinking the shaft.

NEVADA.

Washoe District.

GOULD & CURRY.—Virginia *Enterprise*, Aug. 16: On the 625 level the south drift has been cleaned out and repaired 30 feet; total distance 170 feet.

BEST & BELCHER.—On the 1200 level at a point in the north drift, 525 feet from the south line, upraise No. 1 has been started and carried up a distance of 10 feet. Formation, porphyry.

ALTA.—About 300 tons of ore of the average value of $21.50 per ton, as per battery samples, were crushed the past week. Driftiog northwest of the shaft in ore of fair milling grade on the 1000 level. The 825 and 925 level stopes are yieldiog as usual and looking well.

OCCIDENTAL.—Extracting fair grade ore from the stopes oo the 400 and 450 levels. The winze from the west crosscut on the north line, 550 level, is down 98 feet, the bottom being in quartz and porphyry showing some value.

UTAH.—The main south drift has beeo extended 57 feet; total length, 300 feet. The formation passed through is vein porphyry, clay aod quartz—the latter showing a little value.

ANDES.—On the 420 level a north drift started from No. 1 crosscut is out 67 feet—face in low-grade quartz.

HALE & NORCROSS.—On the 900 level the upraise was advanced 21 feet, making its total hight 45 feet. This upraise is in fair-grade ore.

SAVAGE.—Are extracting ore from the 400, 500, 600, 750 and 1300 levels. Milled during the week 455 tons of ore; average battery assays, $20.50 per ton. Bullion on hand and at the mill, $9059.

YELLOW JACKET.—Prospecting on the 500 and 800 levels being prosecuted with eoergy. Machinery workiog splendidly. Shipping to the Brunswick mill 80 tons of ore daily of the average assay value, as per battery samples, of $21 per ton.

CROWN POINT.—The 300 east stope is looking and yielding about the same as last week. A considerable amount of rock is still coming from the 300 west stope and is composed chiefly of old fillings. Shipped to the mill during the week 775 tons 640 pounds of ore, the average battery assay of which was $16.

BEST & BELCHER.—The 200 north drift from the west crosscut advanced 13 feet during the week, making its length 192 feet. The face is in a mixture of clay and porphyry and streaks of quartz. Have opened the 1000 stope oine sets long by two wide. Will raise the second floor shortly. The 300 stope is up 10 floors from where it was started, and looks well in the top. Shipped to the Vivian mill during the week 274 tons and 630 pounds of ore, the average assay of which was $22 97 per ton.

SEG. BELCHER AND MIDES.—The joint 1300 winze is down 67 feet, having been sunk 19 feet during the week. The bottom is in low-grade quartz and porphyry.

CHALLENGE AND CONFIDENCE.—The joint Confidence, Challenge and Imperial west crosscut No. 2, 1000 level, is out 338 feet, 25 feet having heen made during the week, the face showing quartz having no value. The joint Coofidence, Challeoge and Imperial north lateral drift, same level, is in 520 feet, 33 feet having been made, the face in porphyry.

JUSTICE.—Shipped to the mill during the week 163 toos and 1440 pounds of ore, the average battery assay of which was $31.73 per ton.

IMPERIAL CON.—The joint Confidence, Challenge and Imperial west crosscut No. 2, 1000 level, is out 333 feet, 25 feet having been made, the face in valueless quartz. The west crosscut No. 1, 1000 level, is out 263 feet, having been advanced 23 feet during the week, the face showing porphyry.

OVERMAN.—Extracted and hoisted from the 1300 level 380 toos and 800 pounds of ore. Car sample assays average $19.88 per ton. Shipped to the Brunswick mill 432 toos of ore. Battery samples average $15.88 per ton. Oo Aug. 3d shipped two bars of hullioo; value $9820.06, making total shipments for July account $38,353.64. Amount of ore worked in July 2500 tons. Gross amount of bullion returoed for same, $38,474.43.

CHOLLAR.—Have extracted and sent to the Nevada mill during the past week 426 tons of ore, the battery assay of which averaged $22.72 a ton.

POTOSI.—The south drift from the 1030 winze station is out 140 feet; face in quartz and porphyry. The winze below the 930 level is down 330 feet oo the slope. The bottom is in porphyry with streaks of quartz through it giving fair assays.

WARD COMBINATION SHAFT.—East drift from the 1800 station is now out 482 feet. 10 feet having heen made the past week; face in hard porphyry.

EXCHEQUER.—Work in east crosscut, 150 feet south of the north line, 500 level, is still undergoing repairs. The north lateral drift, 600 level, is out 418 feet; face in porphyry and small streaks of quartz.

ALPHA.—East crosscut No. 2, 600 level, is out

130 feet; face in quartz and porphyry. Southwest crosscut, 600 level, is out 150 feet; face in porphyry with small streaks of quartz through it.

SILVER HILL.—The southeast drift on the 260 level, 240 feet from the shaft, is out 75 feet; face in quartz and porphyry. The northwest drift, 334 level, advanced 20 feet; total distance from shaft, 330 feet; face in hard porphyry.

NEW YORK.—North lateral drift, 800 level, from No. 1 west crosscut, is out 351 feet, face in clay and porphyry. The north drift, 655 level, is out 27 feet; face in porphyry. North drift, 1100 level, is out north of shaft 95 feet; face in quartz and porphyry.

Eureka District.

ORE SHIPMENTS.—Eureka *Sentinel*, Aug. 16: During the week the Eureka & Palisade railroad shipped 165 tons of ore to the Salt Lake City smelters.

Safford District.

THE ONONDAGA.—Eureka *Sentinel*, Aug. 16: The *Sentinel* hears on good authority that matters are soon to be put in operation again in the Ononda ga mine in Safford district, near Palisade. A representative of the company is to be up this week to pay off all the back bills, and it is said that the company will resume under more favorable auspices than it has hitherto known. We hope that there will be no disappointment about it. There are good mines at Safford, and that district is sure to give a good account of itself when the proper effort and capital are expended there.

Tuecarora District.

DEL MONTE.—*Times-Review*, Aug. 15: Very little work has been done during the week, as miners have been scarce, but will resume work at all the different points within a few days.

NEVADA QUEEN.—Raise from the 600-foot level of the North Belle Isle has reached the 500-foot level and a crosscut is being run for the drift and will connect in two or three days.

NAVAJO.—The stopes above the 150-foot level continue to produce the usual quantity of high-grade ore. North drift from No. 1 crosscut south of the shaft, 250-foot level, extended 20 feet. The face is getting harder and shows some low-grade ore.

BELLE ISLE.—South intermediate drift from No. 1 upraise above the 350-foot level, has been extended eight feet alongside of the ledge, which shows good and strong with some concentrating ore making in the hanging-wall. Arrangements for pumping out the 450-foot level are completed and the pumps start to-morrow.

NORTH BELLE ISLE.—The stopes are looking and yielding better. The concentrator is doing very good work, the jig tailings for the week averaging but 75 cents.

NORTH COMMONWEALTH.—Stopes continue to yield about same amount. Have sent to the mill 100 tons, assay value $242 per ton; hoisted and shipped to concentrator 400 tons. Union mill is doing good work on the company's ore.

COMMONWEALTH.—First level—Joint east crosscut extended 17 feet, passing through a vein seven feet wide giving low assays. Have started drifting north on the vein, in seven feet. No. 1 raise from joint west crosscut has been carried up 16 feet. Intermediate drift from No. 6 chute extended 12 feet, exposing two feet of ore, half of it being $234 ore, car sample.

MINERS BUSY.—*Central Nevadan*, Aug. 16: About 300 men are employed in the mines of Tuscarora, and every miner who comes along is set to work. The combination of mines, store, gin-mill and store has been done away with by the new management. This will make Tuscarora a better business place and give the company employes the freedom of spending their hard-earned cash wherever their tastes are best suited.

ARIZONA.

ORE SHIPPED.—Prescott *Courier*, Aug. 16: Steve Mott recently shipped a carload of ore worth between $4000 and $5000; is shipping another carload of richer ore and has the Tuscumbia mill almost ready to run. The Etta mine, near Verde, is opening up well. Reserves of ore are large. It will have a new mill shortly. Dell Thorne's teams arrived here recently with gold sulphurets from the Congress. The gold ledge that was found a short time ago near Iron Springs is said to look very promising. Lots of placer gold have been coming in pretty regularly since the rains made water for rocking and sluicing. Experts have examined the onyx property in Big Bug district and may buy it.

IDAHO.

BLACKFOOT.—Cor. Salt *Tribune*, Aug. 17: The Triumph mine, located a few miles south of Nicholia, on the Little Lost river side of the range there, is showing up finely. This is a low-grade property, almost identical in quality of ore to the Viola mine at Nicholia, which has sent out so much bullion. The Triumph Co. is simply developing to open up a mine large enough to warrant the erection of a smelter. The carbonate and galena ore lies in pockets or blanket deposits from a few inches to 8 feet thick, and like the Viola, may open out a half hundred in places. The ore averages over 50 per cent lead and 10 or 12 ounces silver. It is being developed by tunnels and drifts, in which some 500 or 600 tons of ore has been piled on the dump, and some 5000 or 6000 tons has been exposed by cuttings. A tunnel 200 feet long cuts 100 feet below the known ore bodies, and these will be reached by upraises.

MONTANA.

THE LION.—*New Northwest*, Aug. 16: The Lion shaft was down 291 feet on Sunday last, and it is over 300 feet to-day. The sump will still have to be sunk a few feet and a station put in, occupying perhaps a week, when crosscutting will commence. The vein was struck in the shaft this week, but has not been crosscut. Water has been coming in very strong recently from the north, where the vein is located.

THE PHŒNIX.—The Phœnix Co.'s property is coming to the front as one of the best in Oro Fino district. On Wednesday the miners uncovered as rich a body of ore in the east drift of the 200-foot level as has ever been shown up in the camp. Specimens of ore shown us are estimated as carrying 2000 or 3000 ounces silver. The full extent of the strike is not known as yet. It is safe to say, however, that at a depth of 200 feet there has been nothing to equal it in the district, it being generally conceded that with the amount of work done (225 feet of shaft, 40 feet of crosscuts and 35 feet of levels run) the Phœnix stands at least near if not at the head of the list.

GOLDEN CHARIOT.—Phillipsburg *Mail*, Aug. 16: Joe Thom has lately made a rich strike on the Golden Chariot, which is located on the east side of Dunkleberg creek. The vein is about three feet wide and contains nice-looking ore. A couple of assays were made from samples from the lead, the first-class running from 80 to 100 ounces in silver, and the second-class from 42 to 48 ounces. The ore, as is the case with most all that of Dunkleberg, contains a large per cent of lead and is consequently in demand at the various smelters. The strike had not been made many days before the property had been leased and bonded to the Great Falls Co. Messrs. Scott and J. A. Featherman made the arrangements for the company. The rock is said to be a green chloride and yellow carbonate and the formation is slate.

NEW MEXICO.

COPPER.—Silver City *Enterprise*, Aug. 16: Two carloads of copper ore were shipped from the Hidden Treasure mine at Hanover since last Saturday. Careful sampling shows the mineral to contain 40 per cent of pure copper.

IRON.—Scattered along the crest of the southeast spur of Legal Tender Hill there are 7000 tons of iron ore stacked up awaiting shipment to Socorro and El Paso as fluxing material for the smelting establishments located at the points mentioned.

PACIFIC GOLD.—Reliable information is to the effect that the Pacific G. M. Co. has leased its property to J. C. Carero, a noted mining expert, who for a long time past has been in charge of the Bennett mine in the Organ mountains. This is one of the most noted properties in Pinos Altos district.

LONE MOUNTAIN.—Reports from Lone Mountain are very encouraging to the mine-owners as well as the prospectors. The Mammoth, one of the old reliable standbys, continues to yield its precious metals as of old. The management under the immediate supervision of Frank Bisbee, a large owner in the property, has been very successful; the next shipment to be made in a few days will run considerably over $2000.

CENTRAL.—Lindaur & Woods of Central have had a run of 12 tons of ore from the St. Helena mine in the Wagner mill at Pinos Altos, by Stanley & McDonald. The ore ran at the rate of an ounce per ton; the concentrates, of which 600 pounds was obtained from the run, are valued at $200 per ton.

GEORGETOWN.—The richest ore ever found in the mines is now being taken out of the deep workings on the Scottish Chief ground. The long prospecting incline has been run up to the "Dyke," so plainly discernible on the surface, and as foreshadowed, the strike is of unusual richness.

MANGAS.—The newly organized company are proceeding slowly but nevertheless surely in the development of their property. The workings now approximate 90 feet in depth.

OREGON.

THE SANTIAM MINES. — Albany *Disseminator*, Aug. 16: In 1860 gold was first discovered at Quartzville and some machinery taken in. The works were eventually abandoned, however, and nothing more was done for a number of years. Recently prospectors were sent up from this city and the remarkably fine specimens brought out by them induced capitalists here to form a stock company for the further development of the mines. A company was formed and the stock was soon all taken. Claims were located and for the past 12 months have been worked, the results being entirely satisfactory. Last week the richest leads yet found were discovered. It has been said that there has been prospected an area of 300 acres, upon any point of which a pan of dirt taken will yield from 3 to 10 cents. Experienced miners have examined the ore and pronounced it equal to any ever taken from the great mines of Colorado, Idaho or California. The mines are within a few miles of the Oregon Pacific railroad, and it is only a question of time, and a very short time, when a branch of this line will bring the mines in direct communication with Albany. A steam engine and a five-stamp mill have been taken into the mines and will be in operation next month.

UTAH.

PROSPECTORS.—Eureka *Chief*, Aug. 17: The Northern Spy region is alive with prospectors, and new discoveries will probably be made there soon. Rumor has it that an immense body of ore, rich in native silver, has been discovered on the 400-foot level of the Keystone, several hundred feet north from the shaft. Chas. D. Nelson has a shaft down 23 feet on the Alabama, two miles north of town, and is also doing work on the Shamrock, in the same vicinity, which is looking way up. Work is being pushed on the Seneca group, the property of J. H. and J. P. Driscoll and P. J. Harrington, northwest of town. They have the shaft down 70 feet. The indications are excellent. Will Morris and Tom Jackson went over to the Mount Nebo district the first of the week and located a claim for themselves, Will Kehler and A. Burch. They say they have shipping ore on the surface. J. D. Kendall, manager of the Centennial-Eureka, went to Provo Wednesday to make arrangements to have an electric light plant put in at that mine.

PARK NOTES.—Salt Lake *Tribune*, Aug. 17: The Crescent Mining Co. shipped during the past week 398,500 lbs. of concentrates. J. M. Richardson, Crescent leaser, made a shipment this week of 47,840 lbs. of first-class ore. The Northland-Nevada leasers are again in the field as ore shippers, having sent off this week 53 tons of good ore. Received at Park City Sampler for the week ending Aug. 15th: 527,720 lbs. of Ontario ore; 91,630 lbs. of Daly ore; 106,260 lbs. of Northland-Nevada ore; 238,480 lbs. of Anchor concentrates; 62,340 lbs. of Mayflower concentrates. The Anchor, Woodside, Alliance, Alliance Tunnel and Northland-Nevada paid off this week. The Ontario Drain Tunnel is in a distance of over a mile, and the work is progressing freely. The formation recently changed from porphyry to lime. Although a large number of prospects are being worked at present there is but very little mining news to communicate.

Mining Share Market.

The mining share market has see-sawed the past week, greatly to the disgust of both the bulls and bears—neither side being able to make much of a turn. The news from some of the mines is of a most flattering character, which, combined with an advance in silver, ought to send the stock market well up, but it is the stealings that are going on in some of if not in all of the mines that destroy confidence and neutralize the favorable conditions. It is this lack of confidence that makes it difficult for the ring to make much of a deal—the trading public appears to be too well educated not to unload their holdings or else sell short on every small up move. Yet even with this drawback we still believe in an up move. This opinion is grounded upon the well-established fact that the ring has been forced to buy considerable stocks which they evidently want to sell at a profit, and to do so they will by their system of cross orders advance prices so as to draw in buyers if they can. The ring may even make better reports, higher assays, etc., to bring in a new class of buyers so as to unload at a profit, after which the old, old story.

In outside stocks, the market has been quiet at shading prices for the Tuscaroras and Quijotoas. In the Bodies, Bodie has shown more activity; usually well-informed parties look for a sharp break soon.

According to the sworn statement of the superintendent of the Consolidated California and Virginia mine, there are 207 miners at work in the mine as follows: 96 in the C. & C., 79 Con. Virginia and 32 Ophir. A Comstock miner informs us that the 96 are working from the 1600 level down, the 79 above that level, but the 32 he cannot place, unless they are stoping out ore from the Ophir mine, but then the Con. Virginia Company has them hired. Another miner says they are doing secretive joint-work.

A correspondent asks if the mill ring does not see the handwriting on the wall: "Mene mene Tekel, Upharsin." Thou art weighed in the balance and found wanting.

Reliable private news from the Comstock mines continues hard to get. There are all kinds of rumors afloat, but when sifted they are not deserving of credit. Official advices report more activity and a brighter outlook for the Gold Hill mines since the 800-foot level Yellow Jacket north drift has made connection with the Con. Imperial shaft, but whether outside stockholders will be benefited is an open question. This connection gives ventilation and opens up a wide area for active prospecting, for which purpose more miners are to be put to work. Crown Point's battery assays are now below $15 a ton, Overman's and Belcher's are slightly lower. There is active prospecting in the latter mine. The superintendent of Kentuck reports an improvement on the 1000-foot level both east and west, with more mineral quartz coming. In the east drift it is white quartz; it goes $9.59 in gold and $1.80 in silver. In Savage the official letter reports the ore 24 feet wide, which they are now hoisting to mill. As the ore goes over $40 a ton, the battery assays ought to be about $30 a ton. In Hale and Norcross the prospecting work is more encouraging. In sinking the winze in Ophir they ran into old workings, which, it is said, they have since passed through. The outlook is said to be encouraging when they drift west. There are mysterious hints about Con. Virginia, Best and Belcher and Sierra Nevada. In Potosi and Bullion the work now going on ought to make itself felt soon in the stock market.

Everette's Mining Office.

The Everette mining office and assay chemical laboratory, located at Tacoma, Washington, is one of the best equipped offices on the Pacific Coast. The laboratory is commodious and contains from 4000 to 5000 specimens, the product of mines all over the world. A very interesting exhibit is made of the specimens from Western mines, and especially those of the coast. Dr. Everette has a very extensive library containing 400 of the best works on chemistry, assaying, mining law, mineralogy and geology. There are crucibles, scorifiers and other assaying apparatus of the best designs. Here is also one of the largest stocks of chemicals found in the Northwest. At one end of the laboratory is a battery of four blast furnaces for assaying and smelting. Here is also a pyrometer for nace where the fusing points of substances can be ascertained. Then comes a large crucible furnace—probably the largest on the coast. Dr. Everetto informs us that all mining men and investment-seekers are invited to visit his office, where he will give any legitimate information regarding the mineral resources of any district.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

H. KELLEY—Modoc and Lassen Cos.
T. M. STACKUS—Sierra Co.
J. W. PURDY—Sonora, Cal.
GEO. WILSON—Sacramento Co.
FRANK S. CHAPIN—Lake Co.
J. C. HOAG—San Francisco.
J. G. H. LAMPADIUS—Santa Cruz and San Benito Cos.
SAMUEL CLIFF—San Luis Obispo Co.
W. W. THROBALDS—Orange and San Diego Cos.
C. J. WADE—San Bernardino Co.
J. H. CROSSMAN—San Bernardino Co.
JOHN B. HILL—El Cajon, Cal.
E. B. TAFT—Tulare Co.
W. B. FROST—Merced Co.
E. H. SCHAEFFLE—Calaveras Co.
T. B. DAPRAY—San Francisco.
O. N. CADWELL, Carpinteria, Cal.
WM. M. HILLEARY—Oregon.
JOHN SIMPSON—Oregon.
WM. HOLDER—Oregon.
E. E. DEMING—Ashland, Oregon.
L. CASS BROWN—Oregon and Washington.
R. G. BAILEY—Washington.

SAN DIEGO is now getting its coal from Puget Sound instead of Newcastle. A line of steamers will be established carrying coal down the coast and fruit and grain back.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING AUG. 12, 1890.

434,074.—MAT FOR FERMENTING VATS—C. Bazus, S. F.

434,142.—CONDUCTOR'S PUNCH—A. W. Coffin, S. F.

434,251.—ADDING MACHINE—D. L. Craig, Silver King, A. T.

434,731.—TRACTION ENGINE—J. B. Harris, Stockton, Cal.

434,417.—CLOTHES HOOK—Chas. Hill, Portland, Ogn.

433,943.—JOINTS FOR SUCTION PIPES, ETC.—W. P. Humphreys, S. F.

434,339.—CARTRIDGE SHELL LOADER—C. A. Hussey, Ft. Bidwell, Cal.

434,064.—SPRING MOTOR—Jno. Isele, San Diego, Cal.

434,734.—MITER BOX—A. E. McMillan, Oakland, Cal.

434,352.—CROSSCUT SAW—W. A. Miller, Wapimita, Ogn.

434,135.—ROTARY BLOTTER—E. E. Park, S. F.

434,356.—TYPE WRITER COPY-HOLDER—Pipes & Pernot, Corvallis, Ogn.

434,401.—NAILLESS HORSESHOE—S. Pruden, Los Angeles, Cal.

434,369.—OPERATING PUMPING ENGINE—J. F. Whiting, Albany, Ogn.

The following brief list by telegraph, for Aug. 19, will appear more complete on receipt of mail advices:

California—Frederick H. B. Babbe, Santa Rosa, portable bedstead; Mora M. Barrett and J. F. Daily, S. F., gas or vapor engine attachment; Isaac K. Clever, Deadwood, hanging-up attachment for stamp batteries; Richard E. Eads, Gerson, and A. J. Eads, Pomona, animal trap; J. Weaton, Placerville, bandle for hammers, mallets and other striking tools; Milo P. Holmes, S. F., lifting-jack; Oscar A. Horner, assignor of one-half to R. B. Emerson, Eureka, gun sight; William F. Mitchell, S. F., leaf twiner; Emil F. Moening, S. F., safety device for elevators; William D. Nelson, Traver, slat protector for drapers; George Pardy, deceased, W. Pardy, S. F., executor, riveting machine; Frank Rademacher, assignor of one half to H. H. Leithad, steam condenser and water heater; Josiah H. L. Tuck, S. F., subsoil irrigator and fertilizer; George E. Woodbury, S. F., belt or apron for ore concentrator; Dueber Watch Case Manufacturing Co., Canton, Ill., Cincinnati, O., Newport, Ky., Chicago, Ill., New York, Boston, Mass., and San Francisco, composition watch cases. Oregon—John T. Durkee, Portland, fireproof paint; Peter Wilhelm, Portland, stove-lid and center piece and lifter therefor; Thomas C. Wilkins, Independence, harvester. Washington—Charles O. Heacock, Tacoma, tool-box.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

TRACTION ENGINE.—Jerome B. Harris, Stockton, assignor of one-half to John Gambetti. No. 434,131. Dated Aug. 12, 1890. This patent covers an improved form of driving mechanism for traction engines. The object is to so arrange the driving mechanism that when called into action, and while operating, the dead weight of the frame and the carried parts is transferred from the axis of the carrying or driving wheels to a point outside of, or beyond said axis, and near the wheel's rim, whereby said weight is utilized to assist the positive power in turning or driving the wheels. By the construction employed, when the machine is starting and advancing it has not only the positive driving power of the engine, but also a supplementary power constantly acting and due to the weight of the machine bearing down on the wheel near its rim.

ROTARY BLOTTER.—Edward E. Park, S. F. No. 434,135. Dated Aug. 12, 1890. This device is for use as an ink-blotter. It consists of one or more cylinders built up of endless tubular sheets of blotting-paper or material increasing in diameter so that each exterior tube may be slipped over the interior ones, and in a frame-work in which one or more of said devices may be journaled. Whenever the superficial porous tube has become so much saturated that it ceases to be of use, it is only necessary to cut it with a knife and remove it, when a fresh surface will be presented, which will be used in like manner until worn out. These cylinders being made in quantity, can be supplied to the trade, and it is only necessary to purchase them and introduce them into the handles or holders whenever necessary.

CONDUCTOR'S RECORDING PUNCH.—Arthur W. Coffin, Oakland, assignor to the Coffin Combination Punch and Ticket Co. No. 434,142. Dated Aug. 12, 1890. The object of this invention is to provide a simple and efficient conductor's punch capable of carrying within itself a necessary number of tickets and their duplicates, both of which in their simultaneous passage through the machine are similarly marked or punched, one being given to the passenger and the other retained in the machine.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, $3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

MECHANICAL PROGRESS

Electro-Deposited Copper Steam Pipes.

We have already made brief reference to the Elmore copper-depositing process by which copper steam pipes are made free from welds or joints of any kind. It is well known that the ordinary copper steam pipes are a great source of annoyance and failure, and it must be an extreme satisfaction for steam-users, who have heretofore employed copper pipes under high pressure, to learn that they will soon be able to obtain those of a much superior and most satisfactory quality. The material of these electro-deposited pipes is described as perfectly wonderful, for it is said to have a tensile strength of 25 tons to the square inch, with an extension of 20% in breaking.

These pipes seem to offer absolute security even with the very high pressures now employed. According to *Engineering*, each pipe has etched upon it the results of a test which is made of a strip cut from its end, and thus the engineer is relieved from anxiety as to how it will behave. Even without this guarantee he could have little cause for anxiety, for the process of manufacture does not admit of any irregularity of chemical composition. The pipe consists of pure copper, free from admixture with other metals, and the only variation which can occur is in its hardness. It is possible to secure hard or soft metal at will, according to the purpose for which it is to be employed, and of course it is important that the hard varieties should not be used for steam pipes.

Every one is aware that copper can readily be deposited from its solutions. Practically all the crude copper which comes into this country is refined by electric deposition. By means of currents derived from large dynamo machines the Chili bars are dissolved, the pure copper being thrown down on the cathodes in rough nodular masses, and the impurities, often containing gold and silver, being left as mud in the bath. Hence it costs but little more to deposit the *tubes* direct from the crude Chili bars than it does to purify these bars by the same mode of deposition in the first place. The cost of purification is saved and the additional cost of the manufacture relates chiefly to engine-power and rent, labor being comparatively an insignificant item. When a mandrel is put into a tank it remains there for one or several weeks, slowly turning round, and only needs the slightest attention until it is ready to be lifted out and to be replaced by another. All this time the process goes on automatically, and there is scarcely any expense except that for driving the dynamo. It is certain that this cannot be great per pound of copper deposited.

In the old method the refined copper has afterward to be melted, with the chance of oxidizing it, cast, and rolled into bars or sheets. If it is desired to obtain the copper of soft quality and even texture, it is necessary that the process be carried on very slowly indeed. If any attempt be made to hurry it, the result is a coarse, granular metal entirely wanting both in strength and ductility; hence the imperfection in the present method of making copper pipes.

The Elmore tubes are deposited on a properly prepared core at the rate of $\frac{1}{40}$ inch in thickness per week of 144 hours, or 6 pounds per square foot of surface. The process by which they are produced differs only in one respect from that hitherto followed in the electro-plating of rollers for calico-printing machines. The surface of the copper is continuously burnished by an agate the whole time, and as rapidly as the particles of copper are formed they are rubbed and matted into those beneath and beside them, thus forming a fibrous plate of perfectly uniform structure and great strength. So closely are the particles interlaced that the specific gravity is increased until a plate one-eighth of an inch thick weighs 6 pounds to the square foot. As the mandrel on which the tube is formed rotates in the bath of copper sulphate, the agate travels along it, forming a fine spiral on its surface, the speeds being so arranged that only a very fine film can form between two applications of the burnisher to a given spot.

The physical properties of the metal depend, to a certain extent, upon the rate of deposition and the thickness of the film burnished. This last is usually 7-1000 inches, but it is subject to variation. For instance, steam tubes are usually thickened up at the ends for the flanges to be attached to them. To this end, the anode of common Chili bars is placed nearer to the ends of the tube than to the rest of the length. The electric resistance is therefore decreased at those points, the result being an increased density of current and a thickening of the tube. The ends are thus rendered thicker and softer, so that they can be very readily flanged. These flanges do not serve alone for the union of successive lengths of pipe. Gun-metal flanges with grooves in their faces are first slipped over the cylindrical tubes, and then the ends are rolled over into these grooves, into which they fit exactly. By varying the position of the anode, other alterations of form can be effected. For instance, when it was intended to bend the Elmore tubes by the ordinary process it was proposed to make them thicker down one side than the other, so that the stretching which takes place on the other side of the bend should not reduce the general strength. To do this, the mandrel would have been mounted eccentrically, the result being that the side which approached nearest to the anode would have been the thicker of the two. However, since the introduction of the Fowler bending machine it is not necessary to do this. This machine, an American invention, will bend a pipe of any size without extending the metal on the outer side of the curve. In place of this, it sets up or thickens the metal on the inner side.

Electrically deposited burnished copper may be applied for many purposes besides steam pipes. Indeed, since all copper is electrically deposited, and the burnishing only takes the place of remelting and casting, it is quite possible that the new process may serve for the preparation of every variety of copper goods, and copper electro-plated goods as well.

THE LINK MOTION THE BEST.—A committee of the American Railway Master Mechanics' Association, in a report on the efficiency of the link as compared with other valve motions, state that nowhere is "the survival of the fittest" more pronounced than in railroad practice, and that in America the link has outlived all its rivals. It has, they say, been urged against the link that it is not a scientific or true mechanical motion. This may be true, but the fact remains that fairly good results are obtained from it; that it will take more punishment in the shape of rough usage and neglect, and cost less to make and repair, than any form of valve motion now being experimented with on locomotive engines. They further state that poor results obtained from a locomotive are often unjustly charged to the valve motion, when the cause may be found in contracted steam ways, leaky valves and pistons, and similar defects; and in conclusion they add that no valve motion brought before them is more efficient for all-round work and general utility than a well-designed link with large bearing surfaces. As for the Strong valve gear, for which very high claims have been made, Mr. Ross Kells of the New York, Lake Erie & Western road reports that on his line they have found the link motion fully as economical in coal and more economical on maintenance of the valve gear.

PRESS FORGING.—The distinction between melted metal flowing into molds by gravity and being forced into molds by pressure, when only softened by heat, is not so great as people imagine. The first is as old as civilization; the latter is a new process, developed and made possible by implements of recent invention. All over the world, press forging is increasing. Presses to exert thousands of tons are now common, and the most intricate forms are produced by the flow of metal heated only to redness, the same as it would be for hammering. Even in San Francisco a good many things are being forged by pressure that were formerly cast, notably the parts of "cable grips" and like things are produced by "presses," nearly as cheap as castings of malleable iron or steel. The latest things in such forgings are railway axles. Blanks of a uniform section are placed in dies which form a matrix, having the form of a completed axle, with its necks and collars. Powerful plungers driven by hydraulic force act on the ends of the blank, forcing or "flowing" it into the mold, just as castings are made of fluid metal. The work demands celerity to prevent cooling by radiation, but the process is no doubt a practical and economical one.—*Glasgow Engineer.*

MECHANICAL DEVICES.—Perhaps, says a contemporary, one of the best examples of a mechanical device working its way into great prominence against early prejudice is found in the steam pump. When the late Henry R. Worthington invented his direct-acting steam pump and proposed to use it for feeding boilers, he was met by eminent engineers to whom he showed it with the remark to the effect that, while it was ingenious and all that, no one wanted such a pump. This was the first reception of a machine which, in various forms and modifications, made by different manufacturers and for different purposes, is in use in every civilized country in the world and on board every steamship. No one doubts its utility or its influence on mechanical progress. Perseverance won in the instance of the steam pump, as it has in the instance of many another invention. It is not wise to drive bull-headed against all mechanical opinion, and it is equally unwise to be turned aside by every contrary opinion. Mr. Worthington's belief in himself has been an excellent thing for the world.

IN WORKING STEEL BY HAMMERING, or drawing it down by the process of rolling, it is a well-known fact that the steel forming the corners becomes more dense by the operation, or has the appearance of being refined, for where drills for cutting stone are used they are found to work much better by having the bit or cutting edge come in line with those compressed edges. In rolling eight-square steel, the line of dense metal comes in the form of a Maltese cross, and as the bit of a rock drill, where power drilling is made use of, is something of the same form, care is taken to have them coincide. The etching process must show this action of steel perfection, if a section could be worked off true and even and polished; after hardening, the etching fluid will take hold of the softer metal with greater freedom, bringing out all the features that can be contributed to the action of the hammering or the refining from the rolling operation.—*Ex.*

SCIENTIFIC PROGRESS.

The Planet Venus.

The Italian astronomer Schiaparelli, who recently discovered the fact that Meronry performs only one rotation on its axis during its entire revolution around the sun, and who has made more discoveries in our planetary system within a few years than all other astronomers put together, has just announced another important discovery. He now asserts that Venus, the brightest of all the planets, the twin sister of the earth, also turns but once on its axis in the course of a revolution around the sun. In other words, there is no alternation of day and night on Venus, as on the earth. The planet enjoys perpetual day on one side of its globe, while the other side is plunged in unending night, just as is the case with our moon.

Astronomers have heretofore believed that the time of Venus' axial rotation corresponded almost exactly with that of the earth's. This was supposed to have been established by noting the return of spots visible on Venus to a similar position night after night, but Schiaparelli shows that these observations have probably been misinterpreted, and that instead of indicating a rotation period of 24 hours, they rather confirm his conclusion that the rotation is performed in 224 7 days, which is the time the planet takes to complete a revolution around the sun.

Schiaparelli says the axis of rotation of Venus is nearly perpendicular to the plane of the orbit. If that is so, Venus has no diversity of seasons such as the earth enjoys. Its equator forever burns with the heat of an unending summer, and its polar regions undergo no change of temperature. The equatorial heat on Venus is vastly greater than that on the earth from the fact that her distance from the sun is only two-thirds that of the earth. Moreover, the fact that her heat is unbroken by the alternations of night and day must still more greatly intensify the temperature of the sunny side of that planet. The cold of the opposite side must also, for the same reasons, be greatly intensified.

There may, however, be some modification of the direct and continuous heat of the sun on Venus. All telescopic observations of the planet testify to the blinding brilliancy of its surface, and the most reasonable hypothesis yet put forth to account for this phenomenon is the existence of an extraordinary amount of cloud in its atmosphere.

Anybody who has watched a sun-illumined cloud knows how splendidly it reflects the light, and, of course, in looking at the clouds of another planet, we can practically see only their sunny side. If, then, as appearances indicate, Venus' atmosphere is largely filled with clouds, the effect would be to screen off the superabundant sunshine, and perhaps render even perpetual daylight far less obnoxious than we might, at first sight, be disposed to regard it. There are reasons for thinking that the atmosphere of Venus is most abundant. Its depth has been calculated to exceed that of the earth by about one-third, although Venus is a slightly smaller planet than ours. The existence of watery vapor in this atmosphere has been clearly established by spectroscopic examinations. Of the extent or even the existence of oceans on Venus we know nothing by direct observation, but since the planet possesses an atmosphere and clouds, it is not unreasonable to conclude that it must have oceans capable of supplying the needed vapor.

Coloring Metals by Oxidation.

The cause of the appearance of annealing colors has generally, although without proof, been ascribed to the oxidation of the iron. Herr S. Stein, well known from his experimental investigations of iron and steel at high temperatures, in the *Deutscher Ingeniure*, has now conclusively shown that belief to be well founded. Pieces of iron and steel were carefully cleaned with alcohol and ether and put into a glass tube; the air was exhausted and replaced with pure nitrogen, which was also pumped out in order to secure a thorough removal of the oxygen. The tube was then gradually heated, and as hydrogen and nitrogen generated from the metals they were pumped out. The inner surface of the tube, on its cooler parts, became covered with a white precipitate of a still unknown nature. The whole scale of the temperatures appropriate for the appearance of the annealing colors was tried, but these failed to appear, whereas they were called forth immediately on the admission into the tube of air with oxygen. Herren R Schwirkus and F. V. Lichtenstein have demonstrated in an experimental way that an increasing hardness of the steel necessitates an increasing heating to produce the same annealing color, and that the composition of the steel affects the conditions for the appearance of the different colors in a still higher degree than the hardness. The combinations of temperatures and colors in the ordinary manuals are thus entitled to only conditional correctness at best. Another series of experiments, relating to the influence on the colors of the duration of the heating, manifested that they can appear at even very low temperatures if they are only kept up long enough, and that the difference between hard and soft steel asserts itself here too. A soft piece exposed during several days to the heat of 177° C. showed purple after 68 hours, violet after 93, and dark blue after 120, whereas a glass-hard piece turned light yellow after 20½ hours, dark yellow after 27, orange after 50, and purple after 103. At higher temperatures, the colors appear with shorter intervals.—*Iron.*

A LADY'S LOVE FOR ASTRONOMY.—A New York lady, Miss C. W. Bruce, offers the sum of $6000 during the present year in aiding astronomical research. In the hope of making it of the greatest benefit to science, the entire sum will be divided, and in general the amount devoted to a single object will not exceed $500. Precedence will be given to institutions and individuals whose work is already known through their publications, also to those cases which cannot otherwise be provided for, or where additional sums can be secured if a part of the cost is furnished. Applications are invited from astronomers of all countries, and should be made to Prof. Edward C. Pickering, Harvard College, Cambridge, Mass., before Oct. 1, 1890, giving complete information regarding the desired objects.

TURPENTINE FOR MICROSCOPICAL PURPOSES. As it is very difficult to obtain clear, nice turpentine for microscopical purposes, the following method of purifying it is recommended: Take one pint of the common turpentine and mix in a quart bottle with four fluid ounces of 98 per cent alcohol. Agitate well, and let stand until the two fluids separate. Decant the turpentine (which will form the lower layer) from the alcohol and mix it with one pint of clear water. Agitate thoroughly, and let stand until these two fluids separate, then from the water decant the turpentine (which this time will form the upper layer), and, finally, mix with the turpentine about one ounce of powdered starch, and filter through paper.

THE ARC IN THE TREATMENT OF ORES.—A special dispatch from St. Paul, of July 17th, says: C A. Dalgh of the Westinghouse Electric Company, has been in Tower, Minn., at the iron mines, for the last week, experimenting with electricity and iron ore in the interest of his company. He declares that he has discovered a process by which he can center the rays of an arc light upon a piece of iron ore and thereby soften it to such a degree as to be able to work it with a greatly reduced amount of labor. It has not as yet become known with what success his labors have met.

A NEW PROCESS FOR CHROME IRON.—A Norwegian engineer, Herr O. Olson, Christiana, has obtained a ten-years patent for a new process for the manufacture of chrome iron. In his process, a well-mixed proportion of finely pulverized chrome ore, powdered charcoal and tar are heated to red heat in a closed vessel, then allowed to cool, and finally remelted in a crucible, together with a certain proportion of pulverized iron ore, powdered charcoal, borax, ground glass, and cyanide of potassium. The proportions of the mixture are naturally kept a secret.

A NEW RAILROAD TIE.—A novel crosstie has just been patented by a Covington (Ky.) inventor. It consists of steel or wrought-iron tubing 8 inches in diameter and 12 inches long, fitted with proper supports to fit the rail on top and to rivet to a support at the bottom. Each tube has paper forced into it and guarded against moisture. Each piece of tubing acts as a cushion and support to the rail, while between the rails and securing these cushions is a substantial strip of iron. Great durability and strength are claimed for these ties.

SEEING SOUNDS.—M. Pedrone, a physician of Nantes, France, claims that he has the strange gift of being able to see the color of sounds. He says that human voices are red, blue, black, tan, slate and all colors, and that the color of some handsome women's voices is like that of buttermilk.

BIRD SONGS.—It is proposed that a permanent record be made of the songs of birds by means of the phonograph. "This done," says a correspondent, "the song could be reproduced leisurely and 'scored' by a competent musician. Thus art and nature would go hand in hand."

CYCLONES.—The conclusions reached by modern meteorologists are that cyclones of great intensity are ascending spiral whirls of wind having a rotary motion in a direction in the northern hemisphere opposite to the movement of the hands of a watch.

A WATERSPOUT formed on the bay off Escanaba, Mich., one day last week, lasting 15 minutes. It was 200 feet in diameter at its base, extending into the clouds, and made a noise audible at a distance of two miles.

THE Broken Hill Proprietary Mining Co. of Queensland, the noted silver property, had a net profit in its operations for the half year ended June 30, 1890, of no less than $2 350,000, of which the shareholders received $2 320,000 in dividends, or nearly as much as the famous Ontario mine has paid in, in 170 dividends The total of dividends and bonus is no less than $11,080,000. There is also silver bullion on hand unsold, valued at $475,000, with supplies valued at $500,000.

THE Payne break in the Sacramento, a few miles below Boruck, is about 20 feet deep, and the cost of repairing it will be about $20,000.

GOOD HEALTH.

Health of the State.

The report of the State Board of Health for July contains reports from 100 cities and towns with an estimated population of 850,440. The number of deaths in these towns was 1132, or an annual mortality of 15 96, a somewhat increased rate over the report for June. The increase is attributed largely to stomach and bowel disorders incident to the season. The increase of temperature is also supposed to be an additional contributing cause.

Cholera infantum is reported to have caused 82 deaths, which is the largest mortality in any one month this year. The deaths from this cause in June numbered 51 and in May only 6, showing conclusively how much the disorder is influenced by increased temperature.

Heart disease caused 74 deaths. Cancer is credited with 37.

The Asiatic Cholera.

This dread disease shows no sign of abatement in Spain; on the contrary it is spreading; but, says the report, we are more concerned about its approach nearer home, the disease having made its appearance in Japan, with which country we are closely allied by commercial and industrial intercourse. We would call especial attention to the following paragraph in relation to this disease which we copy from the report:

The disease having been so clearly proven to be contagious through excretions from the infected body, the utmost vigilance will have to be exercised to prevent the transportation of these poison germs to our shores. But suppose all vigilance fails and cholera suddenly appears in our midst. The question that should present itself to every community in the State at this moment is: Are we prepared to repel the invader; are our cities, towns, hamlets and individual premises in such a state of order and cleanliness that disease can find no accumulated filth in which to incubate its germs? If they are, we have nothing to fear, as it has been stated by good authority that the cholera germ is innocuous when it leaves the human organism, and that it requires another medium outside of man to mature and complete its infective properties. That medium is a soil moist and saturated with impurities. If this assertion is true, it necessarily follows that the most complete safeguards against the spread of cholera are a clean soil, untainted air and pure water. The first may be attained by proper drainage, removal of superincumbent filth, garbage, all accumulations of dirt within or near our dwelling-places. Health boards and health officers should now be more vigilant than ever, and enforce, with all the power the law gives them, the proper cleansing of the districts under their charge. They are the officers accountable to the people for the preservation of their lives when threatened by disease.

COFFEE AS A STIMULANT.—It is asserted by men of high professional ability that when the system needs a stimulant, nothing equals a cup of fresh coffee. Those who desire to rescue the dipsomaniac from his cups will find no better substitute for spirits than strong, newly-made coffee, without milk or sugar. Two ounces of coffee, or one eighth of a pound, to one pint of boiling water, make a first-class beverage, but the water must be boiling, not merely hot. It is asserted that malaria and epidemics are avoided by those who drink a cup of hot coffee before venturing into the morning air. Burned on hot coals, coffee is a disinfectant for a sick-room.

DANGER IN THE PHONOGRAPH.—The Fairmount Park Commissioners at Philadelphia have ordered the phonographs banished from the park as a sanitary measure. The objections raised to it are that it is injurious to the public health, not only on account of a liability to cause deafness, but because of a liability to transmit disease of the ear by an indiscriminate use by the public of the ear-pieces. It was further claimed that the insertion of the hearing-tube into the ear is conducive to the contraction of various diseases of the blood owing to the contact which the tube must have with the membranes.

DIED FROM A BEE STING.—A correspondent writes the New York *World*: "I see by this day's issue that a lady in Jersey City died of blood-poisoning, resulting from a bee sting. Had she gone into the nearest laundry and rubbed the part affected with an indigo bag, she would now be alive and well of the sting. It is an effectual remedy. I know several cases where indigo applied in that simple manner cured. Perhaps you will give this a place in your valuable journal, and some of your thousands of readers may have cause to bless you."

REMEDY FOR NEURALGIA.—A correspondent who has been greatly troubled with neuralgia, after trying various remedies without success, finally found relief in the following: Dissolve one-half of an ounce of nitrate of ammonium in eight ounces of water; take one-half an ounce every four hours. In his case this gave immediate relief.

CANCER.—It is important to note that there is only one instance of death of a centenarian from cancer. It seems that the liability diminishes from about 45 to 55 onward, and that after 70 there is but little to fear in this direction.

USEFUL INFORMATION.

A FIREPROOF WHITEWASH.—It is found, says the *English Mechanic*, that a most effective composition for fireproofing exterior surfaces may be formed by slaking a sufficient quantity of freshly burned quicklime of the best grade, and when the slaking is complete, there is added such an amount of skim milk, or water in its absence, as will make the liquid of the consistency of cream. To every ten pounds of this liquid is added separately and in powder, stirring constantly, the following ingredients in the order named: Two pounds of alum, 24 ounces of subcarbonate of potassium or commercial potash and one pound of common salt. If white paint is desired, no further addition is made to the liquid, though the whiteness is found to be improved by a few ounces of plaster of Paris. Lampblack has the effect of giving it a number of shades, from slate-color to black. Whatever tint is used, it is incorporated at this stage, and the whole after being strained through a sieve, is run through a paint-mill. When ready to apply, the paint is heated nearly to the boiling-point of water, and is put on in its hot condition. It is found that the addition of a quantity of fine white sand to this composition renders it a valuable covering for roof and crumbling brick walls, which it serves to protect.

COWHIDE HORSESHOES, it is said, are fast coming into use in England and in many parts of the continent of Europe. It is claimed for this styled shoe that is much lighter, that it lasts longer, and that split hoofs are never known in horses using it. It is perfectly smooth on the bottom, no calks being required, the shoe adhering firmly on the most polished surface. Its elasticity prevents many sprains, the horse's steps being lighter and surer. It is said that straw, treated with chemicals unknown, has been used for horseshoes for centuries in Japan.

DEEP SHAFTS.—The deepest mining shaft in the Australian hemisphere is the George Lansel, No. 180, at Sandhurst, which has reached 2640 feet, or exactly half a mile from the surface. The last reef passed through was 2600 feet, and from indications it is believed that it will prove both a large and valuable lode. Sinking has for the present been discontinued. The deepest perpendicular shaft in this country—in fact in the world—is the Combination shaft on the Comstock, at Virginia, Nevada, which is 3300 feet in depth.

ESTIMATING FOR PAINT.—It is found that in painting wood one cost takes 20 pounds of lead and 4 gallons of oil per 100 square yards; the second coat, 40 pounds lead and 4 gallons oil, and the third the same as the second, say 100 pounds of lead and 16 gallons of oil per 100 square yards for three coats. The number of square yards covered by one gallon of priming color is found to be 50; of white zinc, 50; of white lead paint, 44; of lead-color, 50; of black paint, 50; of stone-color, 44; of yellow paint, 44; of blue color, 45; of green paint, 45.

TAKING PHOTOGRAPHS.—In regard to beauty, a photograph tells nothing beyond form of face. A photographer, explaining a lady's antipathy to the camera, said: "Her features are not regular, and she takes a bad picture. Her beauty rests in her deep liquid eyes, coral lips, rich auburn hair, and lovely complexion, qualities precisely which a camera cannot reflect. On the other hand, a woman dull of eye and faded of hair may make a capital photograph, if she has a straight nose and a tolerably good outline of features."

LARGE ESTATES.—It is generally supposed that this country can discount the world in the extent of some of its landed estates; but it appears that Australia may possibly go us better. Three estates were recently advertised for sale in Queensland, the first of which has an area of 454 square miles, of which the rent is $1600; the second has 648 square miles—about 415,000,000 acres—and the third 553. The one most advantageously situated is "within 100 miles of a railroad."

VALUE OF PATENTS.—A short time ago it was revealed, in the course of a lawsuit, that stock in a baking-powder company in New York had reached the enormous value of $4200 a share, the original value of such shares being $100. A few days ago a patent-medicine man sued his wife, and incidentally it was stated that 49 shares of the patent medicine had paid the enormous dividend of $49,000 in one year.

TO REMOVE PAINT FROM SILK.—Paint can be removed from silk goods by first saturating it in equal parts of turpentine and ammonia, then washing it in soapsuds, and letting it dry between blotting paper under a heavy weight.

THE owner of a new tire, made of hollow spring steel, circular, oval or square, thinks that it will succeed rubber tires for wagons or bicycles. It can be fixed on so that it can never come off.

TO CLEAN OILCLOTH.—Use a wet towel pinned over a broom, rub with long sweeping stroke, and polish with a mixture of linseed oil, beeswax and turpentine, rubbing it in well.

ENGINEERING NOTES.

The Nicaragua Ship Canal.

A Triumph of American Engineering.

The inactivity which has for some time thrown a shadow over the Nicaragua ship-canal enterprise has now passed away and preparations are being made for a new and more energetic pushing of the work. Operations have been somewhat delayed on account of the uncertainty of the success of the efforts being made to reopen the harbor of San Juan del Norte or Greytown, as it is now more generally called, the port of entry for the canal at the Gulf terminus of the canal.

San Juan Del Norte was at one time one of the finest harbors in the world, but the flow of the San Juan river down from Lake Nicaragua brought with it quantities of leaves, weeds, plants, trees, etc., which, as years wore on and no attempt was made to clear them away, clung together, formed small islands and thus destroyed a once grand harbor. The land and sand bars thus formed have built a series of barriers between San Juan and the sea, the result being that it is only by navigating a maze of passages that San Juan has for years been reached.

In the inception of the work of reopening the harbor, several well-known engineers were called upon to devise plans and estimate the cost of the reopening. An American, an English and a French engineer each made examination and estimates. The English and French engineers each estimated the cost at from eight to ten millions of dollars—a much larger sum than had been calculated upon by the promoters of the canal.

The American engineer, Mr. Menocal, who is the chief engineer of the canal company, suggested a plan which would not involve an expense exceeding two millions. He proposed to simply build a breakwater some 1800 feet in length, which he claimed would so turn the drift current that the action of the sea in connection with the usual current of the San Juan river would wear away the obstructing sand bar, deepen the channel and keep it forever at the proper depth for navigation. The English and French engineers agreed in the opinion that the breakwater scheme would not work, but that either the one or the other of their more expensive plans would have to be adopted. The canal projectors decided to try the Menocal plan, and have rather held back on the work upon the canal proper until the action of the breakwater should make itself known. This has now been reached with the most satisfactory results and greatly to the credit of the American engineer.

According to the *Journal of Commerce* of this city, on the 10th of July there were eight feet of water at low tide on the bar north of the new breakwater and the Bloefields steamer had crossed in safety and anchored in the old harbor, the first vessel that had crossed the bar in 23 years. The new harbor dredge of the Canal Company has also crossed in safety, also two large tugs and other craft.

Two vessels were in the harbor discharging piles, which will be used in extending the breakwater, which, when completed, will be over 1800 feet long, with 36 feet of water at the end.

The railroad, which is being constructed from the harbor to the "Divide," will be finished by the middle of this month. It is from this "Divide" that the stone need in the construction of the breakwater will be procured.

On the western division the engineers are at work staking out the ground that will be required by the Canal Company. This ground is all held by private parties, and as soon as the Nicaragua Government can place the Canal Company in possession of the property, the construction contracts will be let and the work forced to an early completion.

This great work is being conducted in a very quiet and unassuming manner. There seems to be no want of men or money, and with such a man as Hon. Warner Miller at the head to guide matters, we can all rest assured that we shall in good time see the great ships of the world crossing the continent and bound for San Francisco.

AN AMERICAN-BUILT BRIDGE IN AUSTRALIA. The piers of the great Hawksbury bridge are found to show a lateral movement amounting to 2½ inches at its maximum. This bridge, which is in Australia, and which was built by American engineers and contractors, is chiefly remarkable for having its foundations deeper than any other bridge in the world. The deepest pier is a monolith 200 feet high. Some consider that a small amount of motion is inevitable on the summit of a pier of this hight, while others contend that it shows that the piers have an irregular bearing at their base and probably rest on a ledge of rock at one corner. There is no vertical movement. The bridge is double-track, and trains, some of them double-headers, run over it at the rate of 30 miles an hour. Another theory is, that as the load on a double-track bridge is not exactly above the center line of the pier, a slight rocking may be caused by the vibration set up by the passage of the trains.

A NEW FRENCH CANAL.—The French Minister of Public Works has just inaugurated a canal from the Aisne to the Oise. It has been constructed to facilitate traffic by water between the north and east of France. Although the canal is less than two miles in length, it will, nevertheless, reduce a voyage between the north and east of France by no less than 36 miles. The works upon the new canal comprise two canal bridges, 13 sluices and a tunnel 2628 yards in length. The piercing of this tunnel was attended with many engineering difficulties.

ELECTRICITY.

MOTOR CONSTRUCTION.—The changes which have been brought about and are still going on as a consequence of the introduction of the electric motor afford a most interesting study, not only from the mechanical, but from the social, standpoint as well. The effect seen in the development of the steam engine alone would form an interesting chapter of history, leading to the irresistible conclusion that electric lighting and electric-power have contributed more than any other influence to the perfection of the high-speed engine. High speed was, indeed, necessitated by the construction of the dynamos and motors heretofore generally employed, in order, chiefly, to avoid as much as possible the use of counter-shafting. While the tendency to the reduction of speed in dynamos has made itself felt for some time past, it is but comparatively recently that this idea has gathered force with regard to electric motors. The reasons which have led to this new departure are, we think, not difficult to discern. It is, indeed, but the natural outcome of the endeavor to bring the speed of driver and driven shaft as nearly to uniformity as possible, in order to avoid intermediate gearing, whether it be reducing or multiplying. The direction in which the tendency in question seems likely of accomplishment, practically, is in the employment of multipolar machines.

SLAUGHTERING BY ELECTRICITY.—An apparatus has been devised and patented for slaughtering by electricity. It is claimed by the inventors that their method of killing animals by means of a high-tension electrical current is less cruel and barbarous than the ordinary method. They also claim that the animal bleeds more freely, and that the meat is benefited by the passage through it of an electric current. The inventors state that meat slaughtered by this method will keep longer than by other methods, and that pork slaughtered by electricity is found to be entirely free from trichinæ. The apparatus consists in a pen provided with a metallic floor divided into two sections, an electric generator for supplying a current of sufficiently high tension for the purpose, and a hand electrode for applying the current to the animal. The pen rests upon insulators, and one portion of the metallic floor is connected with the dynamo. The animal to be killed is first driven through a shallow pool of water to wet its hoofs, so as to secure a good electrical contact with the sections of the metallic floor. When the animal stands partly upon each section, it may be killed by bringing the electrode into contact with the rear part of the floor.

THE BOOTBLACK'S INDUSTRY THREATENED.—Another industry which seems destined to be stirred to its very depths by the advent of the electric motor is that of the bootblack. The first blow at what will soon be regarded as the ancient practice of shining by hand has been dealt in Chicago, where electrical blacking machines are now at work on the streets. The outfit is of the simplest description. A small motor is concealed in a box beneath the footrest of the bootblack's chair; a flexible shaft, with one end attached to the armature spindle, has the other fitted with a revolving polish brush. The only other element in the outfit is a push-button, and when this is touched the brush spins round at a speed that laughs to scorn the deftest hand that ever gave the exultant finish to that portion of the morning toilet. The increased capital which the new plant will involve, and the larger amount of business which a single individual may do, will somewhat deplete the number now engaged in that useful occupation.

NEW ELECTRIC MOTOR.—*Practical Electricity* says: "A new electric motor is coming into the field. We have been permitted to see it in operation, and also to study its construction. It is a motor which, if all accepted electrical theories are correct, ought not to 'mote' at all; that it does do this, however, is our justification for speaking of it at this time. Moreover, its efficiency is high, and for a given power its weight scarcely exceeds a third of that of any railway or stationary motor now on the market. As soon as the inventor, who is a gentleman well known in the science, and the company which will exploit the invention shall give us permission, we shall take pleasure in describing the new wonder."

ELECTRICITY A LION-TAMER.—The use of electricity is offered to the lion-tamer in the form of a light wand, with an insulating grip for the hand, connected by a flexible wire with a battery of which the power can be varied at will. An experiment with this form of applied science has been successfully made.

AN OLD INDUSTRY REVIVED.—There are 35 men in Suffolk, Eng., still employed in making gun-flints, or "flint knapping," as they call it, for the use of the remote savages who have succeeded to the long-discarded flint guns and pistols of civilization.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Condensing Steam-Pumping Engine, with Triple Cylinders; Longitudinal Section of Underground Dam; Cross Section of Underground Dam; Gravel Mining, 119. Lead-Smelting Furnaces; Cross Section of Ridge at Shady Run, Showing Elite Con. M. Co.'s Tunnel and Shaft, 127.
EDITORIALS.—A Triple-Expansion Pumping Engine, 119. Passing Events; Milling Comstock Ores; Gravel Mining; Damming Back Water in Mines; Silver Purchases, 126. Lead-Smelting Furnaces, 127.
CORRESPONDENCE.—The Gold Belt of Northern California; San Bernardino County, 120.
MECHANICAL PROGRESS.—Electro-Deposited Copper Steam Pipes; The Link Motion the Best; Press Forging; Mechanical Devices; Miscellaneous, 124.
SCIENTIFIC PROGRESS.—The Planet Venus; Coloring Metals by Oxidation; A Lady's Love for Astronomy; Turpentine for Microscopical Purposes; The Arc in the Treatment of Ores; A New Process for Chrome Iron; A New Railroad Tie; Miscellaneous, 124.
GOOD HEALTH.—Health of the State; Coffee as a Stimulant; Danger in the Phonograph; Died from a Bee Sting; Miscellaneous, 125.
USEFUL INFORMATION—A Fireproof Whitewash; Cowhide Horseshoes; Deep Shafts; Estimating for Paint; Taking Photographs; Large Estates; Value of Patents; Miscellaneous, 125.
ENGINEERING NOTES.—The Nicaragua Ship Canal; An American Built Bridge in Australia; A New French Canal, 125.
ELECTRICITY.—Motor Construction; Slaughtering by Electricity; The Bootblack's Industry Threatened; New Electric Motor; Electricity as a Lion Tamer; An Old Industry Revived, 125
MINING SUMMARY—From the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Wyoming, 122-123.
MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 130
MARKET REPORTS.—Local Markets, Eastern Metal Markets, 130.

Passing Events.

Congress is about to consider a proper classification of mineral lands, a step which, if taken long since, would have saved much litigation between agricultural and mineral claimants. The classification of public lands has been passed upon in a very loose manner heretofore, and a great deal of mineral land has passed from the public domain into private ownership.

The preliminary trials of the new war vessel San Francisco show a very high speed, and it is probable that the Union Iron Works of this city will get quite a handsome bonus for excess in speed. It is to be hoped the San Francisco will show a higher speed than the Eastern-built vessels.

It is probable that public attention to the matter of the destruction of the "big tree" groves of California will result in a withdrawal of all such groves from public entry, as has been the case in the Tulare county section.

Very extensive preparations are being made toward celebrating the 40th anniversary of California's admission into the Union, and it is probable that a good many of the early pioneer miners will come from the mountains to the city on the occasion.

THERE is a blackberry bush on the place of B. Donovan, in Santa Rosa, that measures 16 feet in hight. The vine is now only one year's growth, and Mr. Donovan thinks it will reach the remarkable hight of 20 feet.

THE new cruiser San Francisco, built by the Union Iron Works in this city, has steamed over 19 knots in her preliminary trials in the bay.

Milling Comstock Ores.

The president of the Crown Point Mining Company states that in our editorial which appeared in last week's issue under the caption of "Assays and Mill Losses on the Comstock," we did an injustice to his company. He says that the discount on silver was not taken into consideration when we gave the average yield as per bullion report. The figures given by us were taken from the sworn statement of the superintendent of the company, and were by us considered as reliable, and therefore published and criticised in a friendly spirit. But to allay suspicions of unfairness, we asked the president to give us his figures and any comment he deemed necessary. He gave us the following returns for the quarter ending with June: 9960 tons of ore milled; gross assay value, $156 250.06, which yielded a net return of $137,362.35, showing a discount of $18,887.71. In order to arrive at a better understanding of the situation, we asked for the mine assays and battery assays and the bullion returned as per Mint certificate. Although the law requires that the mine assays be given, no such returns are reported, but the battery and net returns were given as follows by months:

	Tons milled.	Pulp assay. Gold.	Silver.	Net return. Per cent Gold.	Silver.	saved.
April.....	3650	$8 40	$11 16	$6 89	$8 58	78.73
May.....	2860	9 14	12 08	7 02	8 78	74.46
June.....	3450	7 74	10 60	7 03	8 79	85.83

The percentages saved by months were as follows in gold: April, 81.17; May, 76.79; June, 90.88; and in silver as follows: April, 76.88; May, 72.69; June, 82.09.

These figures upon analysis, according to our understanding of the situation, scarcely show the improvement that was to be expected. The discount on silver should, however, undoubtedly, have been considered. It is well to note also that as the amount of taxes is based on the sworn returns that we quoted last week, it is but natural to charge up as expenses all that can be charged such, as office in San Francisco, etc.

It should be borne in mind that our comments on this subject have not dealt with the lineness managements of the companies in any way except as regards the milling of ores. It is that branch of Comstock mine management which is creating dissatisfaction, and the facts concerning which we are anxious to see fully ventilated. There is no intention or desire on the part of the PRESS to do injustice to any men or mines, and in case any statements which are incorrect find their way into our columns, we shall be glad to be put right by those in a position to clear up any doubtful points.

As in the editorial of last week, mention was also made of the Consolidated Virginia ores, we have obtained from that company the July returns of the milling, from the results of which our readers may draw their own conclusions. The figures from the sworn statement published last week showed that the returns from the Consolidated Virginia and California gave an average pulp assay of $22 34 per ton for the quarter, of which they saved 65.35 per cent, or $14 60 per ton. The report of the ore milled by this company for the month of July is now at hand and proves correct our claim that 85 per cent of the pulp assay can be saved when the rock is properly milled. The July report of the two mills that reduced the Consolidated Virginia ore is as follows:

The Morgan mill crushed 3475 tons of ore yielding bullion $50,692. The average of the pulp for the month was $17.20 per ton; the net yield $14.58 per ton, which is 84 77 per cent of the pulp assay.

The Eureka mill crushed 6940 tons of ore yielding bullion $98,731. The average of the pulp for the month was $16.10 per ton; the net yield $14.22 per ton, which is 88 33 per cent of the pulp assay.

The average of these two mills for the month of July is 86.59 per cent, or 21.24 per cent more than the average for the quarter ending June 30th, the difference meaning a loss to the stockholders of this company for that quarter of $168,198 90. The rock crushed in July is presumably of the same character as that crushed in the preceding quarter. The mills are the same, the men operating them the same, and the methods pursued in handling the ore the same. Whereln, then, does this difference lie?

Taking 10,415 tons of the ore crushed for the preceding quarter, and comparing it with the same quantity crushed in July, we find as follows:

Crushing in quarter ending June 30th, 10,415 tons; average pulp, $22 34 per ton; bullion produced, $152,059. July crushing: 10,415 tons; average pulp, $16.65 per ton; bullion produced, $149,423, making a difference of $2636.

These figures show that according to the Comstock milling methods, the same quantity and character of ore worked by the same mills, the same methods and the same men, and yielding $5.69 a ton more, gives only $2636 more bullion!

The mine assay for the July output of Con. Virginia has not been given. It is to be regretted that this has been omitted; we suppose the omission to be unintentional.

It is proper to notice here that while the per cent of the bullion saved from the pulp has increased 21 24-100 per cent, the pulp assay of the rock milled has apparently decreased 25 47-100 per cent. If we had the car sample assays, this difference would be clearer, but in their absence we are left to grope in the dark. We hope that in the future the various companies will obey the law and give these car sample assays, as the stockholders consider them necessary for their enlightenment. We notice that the Overman Mining Co. in their last weekly report has done this, and there can be no reason why the balance of the companies should not do the same.

Gravel Mining.

In this number of the PRESS we conclude the series of articles on "The Gold Belt of Northern California," by Mr. James F. Talbott. These articles are of an eminently practical character, embodying as they do, the personal observations of a man who has been a miner in the gravel regions since "early days." While the articles deal with only one section of the mining region of this State, the deductions are applicable to other gravel-mining regions as well.

We do not remember having seen in print anywhere a better description of the conditions existing in the gravel mines in this State than this of Mr. Talbott. Making no pretense to scientific knowledge, and having no new theory to advance, he has explained to our readers in simple language what has come under his personal observation while working in the gravel mines and seeing the work of others. The indications and surrounding characteristics of the lava-capped ridges where rich drift mines are to be found are pointed out and the courses of the old river channels (as he considers them) are described with accuracy.

While not intended as an answer to the previously published excellent article of Mr. Henry G. Hanks, who holds a different theory of the formation of these gravel deposits, most of the facts stated by Mr. Talbott are in support of the old theory of ancient river channels so long held by the miners of this State. It is to be hoped that others will be induced to enter the discussion of this subject, so important to the mining industry of California, and we should be glad to afford space to any correspondents who have any views to advance.

ACADEMY OF SCIENCES.—At the meeting of the Academy on Monday night, Mr. Vaslet read a paper written by Dr. Edward Palmer of the Agricultural Department at Washington on the customs of the Coyotero Apaches of Arizona. The paper dwelt upon their peculiarities of dress and diet, their habits of living and their social customs. The committee to whom was referred the matter of considering means for preserving the redwood forests of the State presented a memorial to Congress, which they had prepared, setting forth the destruction and threatened annihilation of the sequoia gigantea in this State, and the desirability of some action looking to the prevention of their further destruction. It suggested that all lands upon which there are redwood forests be withdrawn from sale and be converted into national parks. The report of the committee was adopted and further action postponed for two weeks in order to prepare plans and maps to accompany the petition.

A BULLETIN of the Census Department shows that there has been an increase of 6,000,000 tons of pig iron over the figures of ten years ago.

Damming Back Water in Mines.

When a large influx of water occurs in a mine, when the pumps cannot handle it, dams are sometimes built, so that only a portion of the mine will be flooded. Mr. H. A. Gordon, Inspecting Engineer of the Mines Dep't, N. Z., in his "Miners' Guide," shows one of the forms of dam used. The cuts on the first page of the PRESS show this dam. A taper chamber is cut out in the place where the dam is to be built, cutting the rock on the sides, roof and bottom as smooth as possible, in the shape shown in the accompanying cuts. Previous to commencing the excavation on the bottom, a low dam has to be placed across the adit some distance back from the place where the chamber has to be constructed, and the water conveyed in boxes to the shaft or to a point where it will be clear of the place where the work is carried on.

The excavation is then cut out in the bottom and the bottom set of square logs laid in position, with a coating of some soft plastic material, such as cement, to fill up all the pores in the excavation and allow the timber to be firmly bedded. Each layer is laid closely on top of the other, and each log is cut to the same taper so as to fit close together for the whole of their length. Four large baulks have to be fitted to form the center portion or man-hole for the workmen to get out after the whole of the logs are in position, and previously to this the center plug has to be left inside the dam. As soon as the whole of the logs are in position a battering-ram is used on the inside to drive every log home as close as possible.

When everything is ready for the plug to be inserted, a quantity of sawdust and moss, if procurable, should be placed inside the dam. This will, when the water rises inside, be forced into any little crevice in the logs or between the logs and rock, and tend considerably toward making the dam thoroughly water-tight. An eye-bolt is placed in the small end of the plug, whereby it can be drawn tightly into the hole by means of a lever, screw, or any other method that may be deemed desirable. If a dam be properly constructed in this manner, with the timber cut and fitted to the correct taper, it will form a dam that will last as long as the mine is at work. The water makes the timber swell, and very soon the dam becomes thoroughly water-tight. It is even better than either a brick or cement dam (so long as the timber does not decay).

Silver Purchases.

The course of the silver market since the new law went into effect, requiring the Secretary of the Treasury to purchase 4,500,000 ounces of silver a month, is a source of congratulation to bimetallists. The assertions made by monometallists, previous to putting the law into effect, that with an advance in the price of the metal in this country, we would be made Europe's dumping-ground, are not only proven fallacious, but the European countries are drawing supplies from us even at the higher prices now paid.

The tri-weekly purchases of the Treasury have been made at steadily advancing prices, as the following records show: On Aug. 15th all silver offered below $1.15 an ounce was accepted, but the quantity purchased was not given. On Aug. 18th the amount of silver offered to the Treasury Department was 340,000 ounces. The amount purchased was 290,000 ounces, as follows: 40,000 ounces at $1.13.5; 50,000 ounces at $1.12.5; 200,000 ounces at $1.19.75. The local purchases by mints from the 13th to the 16th inst., inclusive, amount to 82,177 ounces. The price of silver in London on the 18th was 54d. This is the highest point reached since April, 1878.

Subsequently offers were received from San Francisco to sell 50,000 ounces at $1.16, and 200,000 ounces at $1.18. Both offers were accepted. This made the total offerings on the 18th 990,000 ounces and the total acceptances 540,000 ounces. On the 20th the amount of silver bullion offered for sale to the Treasury Department was 1,314,000 ounces. The amount purchased was 466,000 ounces, as follows: Fifty thousand ounces at $1.1945, 16,000 ounces at $1.19875, 150,000 ounces at $1 20, 250,000 ounces at $1.2025.

LOS GATOS proposes to have water-works and sewers even if all the capital required is raised at home.

Lead Smelting Furnaces.

In the PRESS of last week a description was given of the furnaces in which the first regular attempt at lead smelting was made in the far West. They were built in 1866. In 1870 three blast furnaces were put up at Hamilton, White Pine, Nev., but were soon discontinued; then at Napias (now Eureka), Nev., a small furnace was put up to work the ores of New York Canyon, but the ores were unsuitable and the attempt to smelt given up. A small draft furnace was subsequently put up to work the rich carbonate ores, and some base bullion made. Buel & Bateman then built stone furnaces to reduce the ores of Ruby Hill, and did so with good results. In 1871, Messrs. W. S. Keyes and A. Arents put up large furnaces at Eureka. These were of the Piltz and Raschette types.

The Piltz furnace originated at Freiberg, in Saxony, and its horizontal section was octagonal; the octagon being flattened at the front or working side of the furnace. It was supplied with seven tuyeres. Fig. 1 shows a section from front to back, and Fig. 2 shows the ground plan. The upper portion was sustained by a cast-iron mantle, so that the interior portion, composed of firebricks, could, when burnt out, be easily removed without disturbing the superstructure. The section of the furnace widens upward toward the feed doors, which arrangement is exceedingly advantageous, in view of the fact that the charge becomes compacted as it descends toward the smelting zone. The gases as they ascend to the upper parts of the stack have an opportunity to expand, thus diminishing their velocity, and for this reason the amount of flue dust is very considerably lessened.

The Raschette furnace is particularly applicable to smelting both lead and copper ores, and is shown in the accompanying figures taken from the *Metallhuettenkunde* of Balling, published in Berlin, Prussia, in 1885. As originally constructed, it had two working fronts, and was proportionately very much longer than it was wide. Fig. 3 represents a side of the furnace; Fig. 4 represents a section through the working doors. It was found that this furnace put through in 24 hours from 40 to 50 per cent more ore than the round furnaces. The upper portion was like the Piltz, supported upon an iron mantle resting upon iron columns. This furnace to-day forms the basis of construction of all the more modern American smelters. As soon as Mr. Arents assumed charge as metallurgist of the works of the Eureka Cons. Co., he sought to improve on both the Piltz and Raschette furnaces, and, as a result, a furnace pictured in the accompanying sketches was built at Eureka, Nev.

Fig. 5 represents a section through the long sides of the furnace, and shows at the left the automatic or siphon tap, which will be further described hereafter; Fig. 6 represents a section from the front to the rear of the furnace through the slag-discharge or working door. The dimensions are given in meters and fractions. One meter equals 3.2809 English feet. This furnace distinguishes itself from all others heretofore built in the following particulars, viz: The introduction of the contracted inclined hosh, which is an eminently rational form of construction, for the reason that when the charge has become molten, and the fuel mixed therewith has fulfilled its office, the smelting material naturally becomes greatly diminished in cubical contents, and requires less space for its accommodation.

In Fig. 5 may be seen the automatic, or, as it is sometimes called, the siphon tap or lead-well of Keyes & Arents. In the sketch the tap *a* is incorrectly delineated, being drawn at too low an angle. It should be so constructed that a bar inserted from the outside will readily pass to the bottom of the furnace, an angle of 35 to 45 degrees being the most appropriate. On page 660 of Prof. Emmons' twelfth volume of the United States Geological Survey this tap is described as "one of the most important inventions ever made in the construction of smelting furnaces."

The accompanying figure, Plate 6, taken from the patent granted to the inventors, shows the exterior basin and the tube connecting it with the bottom of the furnace. As originally proposed by Mr. Arents, this connection was made directly downward from the bottom of the exterior basin to a point level with the bottom of the smelting furnace, and from thence by a horizontal channel. When this device was first attached to the furnace, the building took fire from incautious firing, and water having been poured upon the flames, ran down the side of the furnace and into the exterior tap-basins, chilling the lead and necessitating the reconstruction of the tap-basin and tap canal. On the suggestion of Mr. Keyes, the original right-angle connection was abandoned and connection made at an inclined angle, which long practice has since proved the more desirable form of application.

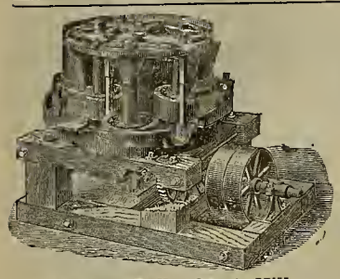
THE CONTROL OF THE COPPER MARKET.—Although the copper mines of Great Britain only produced the first half of the year 395 tons of fine copper, that country controls the copper trade of the world, and its markets establish the price. Great Britain consumed in the first half of this year 37,447 tons of copper, and has on hand now 38,524 tons. The imports into England the first half of this year amount to 66,199 tons of copper.

THE Winnemucca *Silver State* tells of a company of miners that failed in opening a mine at Unionville ten years ago. They assigned their claims and left the property. A few weeks ago the mine was sold to an English company, and the first use made of the money was to wipe out the old debt, although it was outlawed many years.

THE cruiser San Francisco logged 19 75 knots in her run of three hours under forced draft last Saturday. This is not as satisfactory a test as over a measured mile, but from her trials thus far it seems likely that the vessel will earn her builders a handsome premium for speed in excess of the guaranteed 19 knots.

ONE lumberman of Sierra valley, Cal., sold recently 600,000 feet of pine to a Salt Lake firm. It was shipped at Truckee.



Centrifugal Roller Quartz Mill.

F. A. HUNTINGTON.

MANUFACTURER OF

CENTRIFUGAL ROLLER QUARTZ MILLS,

Concentrators and Ore Crushers,

Mining Machinery of Every Description. Steam Engines and Shingle Machines.

SEND FOR CIRCULAR.

Nevada Metallurgical Works.

NO. 23 STEVENSON STREET,

Near First and Market Streets, S. F.

C. A. LUCKHARDT, Manager. ESTABLISHED 1869

Ores worked by any Process.
Ores Sampled.
Assaying in all its Branches.
Analyses of Ores, Minerals, Waters, etc.
Working Tests (practical) Made.
Plans and Specifications furnished for the most suitable Process for Working Ores.
Special attention paid to Examinations of Mines; Plans and Reports furnished.

C. A. LUCKHARDT & CO., (Formerly Huhn & Luckhardt), Mining Engineers and Metallurgists

GREAT REDUCTION!

BATTERY SCREENS.

Best and Cheapest in America.

No imitation, no deception, no planished or rottan iron used. Only genuine Russia iron in Quartz Screens. Planished iron screens at nearly half my former rates.

I have a large supply of Battery Screens on hand suitable for the Huntington and all Stamp Mills, which I will sell at 20 per cent discount.

PERFORATED SHEET METAL

For Flour and Rice Mills, Grain Separators, Revolving and Shot Screens, Stamp Batteries and all kinds of Mining and Milling Machinery, Iron, Steel, Copper, Brass. Zinc and other metals punched for all uses.

Inventor and Manufacturer of the celebrated Slot Cut or burred and Slot Punched Screens.

Mining Screens a specialty, from No. 1 to 15 (fine).

Orders promptly attended to.

San Francisco Pioneer Screen Works, 221 & 223 First St., San Francisco, Cal.

JOHN W. QUICK, Proprietor.

WINCHESTER HOUSE,

44 Third Street, · San Francisco, Cal.

This Fire proof Brick Building is centrally located, in the healthiest part of the city, only a half block from the Grand and Palace Hotels, and close to all Steamboat and Railroad Offices.

Laundry Free for the use of Families.

HOT AND COLD BATHS FREE.

Terms, Board and Room, $1.00 per Day And Upward.

Rooms with or without Board, Free Coach to the House,

J. POOLEY.

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, Aug. 21, 1890.

Geoeral trade the past week has been fairly active. The money market continues to show a fair degree of ease, with all legitimate requirements readily met by hanks and outside capitalists. The high prices of farm product and the advance in silver tend to the easy condition of the market.

MEXICAN DOLLARS—The market has beld stroog at higher prices. Sales are reported at 91¼c from first haods. Over the couoter, sales are made at 92@92½c.

SILVER—Under Mint purchases the price has advanced sharply. The couoter rate is $1.18½; while on direct selling offers over $1.20 was paid yesterday by the Department. All offers are now made to the Department at Washington direct. The prices paid on each huyiog day are giveo in the editorial department of to-day's paper. In this city over one-half of the holdings bave been placed. It is very generally conceded that the stock now on hand will soon be absorbed, when it is not at all unlikely that much higher prices will obtain. It is quite certain that in the Comstock mines gold will predominate as the work in tbem progresses. In Kentuck there is already showing oearly $8 of gold to $1 of silver. The Chinese demand for silver ought to begin to set in soon.

QUICKSILVER—Receipts the past week aggregate 210 flasks. Overland shipmeots in last month aggregate 125 flasks. The market is steady, with a fair demand ruliog.

BORAX—Receipts the past week aggregate 750 ctls., and exports by sea 26,705 pounds to Chicago, 115 pounds to Hooolulu and 600 pounds to Mexico. There was shipped overland in the past month 6580 ctls. The market is firm, with a good Eastern demand ruling.

LIME—Receipts the past week aggregate 4070 bbls. The shipping demaod is fair, while the home demaod shows an increase.

LEAD—The market is strong at unchanged quotations. The consumption on this coast is steadily iocreasing.

TIN—The spot market is barely steady, hut for shipment there is a strong tone. The lower outward freights from the supply market to this city is in shippers' favor.

COPPER—The market has held steady. It looks very much as if producers have determined to keep prices steady so as not to check tbe demand, which higher prices undoubtedly would do. The stocks the world over are being reduced.

COAL—Imports the past week aggregate as follows: Coos bay, 450; Seattle, 840; Tacoma, 4000; Nanaimo, 1300; Sydney, 3060; New Castle, N. S. W., 4390. Total, 13,640 tons. The market shows an advance in Australian, with still higher prices looked for. Although the tonnage to arrive is larger than at this time in 1889, yet it is all cared for, and it is upon this fact that large dealers base their bullish proclivities. Io coast coals the feeling is stronger. The consumptive demand is steadily increasing for all grades.

Eastern Metal Markets.

By Telegraph.

NEW YORK, August 20.—The following are the closing prices the past week:

	Silver in London.	Silver in New York.	Copper.	Lead.	Tin.
Thursday	51⅛	1 12⅞	$16 85	$4 55	$21 00
Friday	52	1 13⅛	16 85	4 60	20 95

PATENTS FOR SALE —Mr. John F. Tilton of this city has for sale the patent right to several of his inventions. He has a patent on a safety attachment for car stoves. By this device the fire in the car stove is extinguished in case the car is thrown over an embankment or otherwise capsized. His patent sewer gas trap is intended to cut off the communication between sinks or hoppers and the sewer. This device is a simple one and not expensive. Another patent is a faucet for shipping and service-cans such as are used for oil, etc. This also is a simple and ingenious appliance adapted for oans or barrels so that the contents can be readily drawn in qnantities to suit from the original package. Mr. Tilton desires to sell each of these patents at prices from $500 to $1000. Information concerning them can be had at this office or from Mr. Tilton at No. 221 Elm avenue. The devices covered by the patents are of that character which come into common use when properly introduced to the public.

EIGHTEEN persons were killed and 30 injured in a railroad accident on Tuesday at Quinoy, on the Old Colony road, near Boston.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, *or beyond the time he intends to pay for it*, let him not fail to write us *direct* to stop it. A postal card (costing one cent only) will suffice. We will not koowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

HANFORD has another artesian well connected with its city water supply. A good flow was struck at 500 feet.

Assessment Notices.

GOVER MINING COMPANY—LOCATION of principal place of business, San Francisco, California. Location of works, near Drytown, Amador county, California.

Notice is hereby given that at a meeting of the Board of Directors held on the 14th day of July, 1890, an assessment (No. 2) of twenty-five cents (25c) per share was levied upon the capital stock of the Corporation, payable immediately to the Secretary, at the office of the Company, 13 and 15 Fremont street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on Wednesday, the 20th day of August, 1890, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on SATURDAY, the 6th day of September, 1890, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

GRAY DEW, Secretary.

Office, 13 and 15 Fremont St., San Francisco, California.

DELINQUENT SALE NOTICE.

GRAY EAGLE MINING COMPANY—Location of principal place of business, San Francisco, California. Location of works, Placer county, California.

Notice—There are delinquent upon the following described stock, on account of Assessment (No. 18) levied on the first day of July, 1890, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Cert.	No. Shares.	Amt.
Bogart, O H, Trustee	423	350	$ 21 00

CERTIFICATE OF PARTNERSHIP.

We certify that we constitute a partnership transacting business in the City and County of San Francisco, State of California, and in this State. Its principal place of business is at San Francisco, California. The name is CONNOR & GRANT. The full names and respective places of residence of all its members are signed hereto, and the said copartnership to commence June 1st, 1890.

SAMUEL B. CONNOR, San Francisco, Cal.
ANDREW S. GRANT, San Francisco, Cal.

STATE OF CALIFORNIA, } ss.
City and County of San Francisco, }

On this 12th day of July, in the year one thousand eight hundred and ninety, before me, Geo. T. Knox, a Notary Public in and for the City and County of San Francisco, personally appeared Samuel B. Connor, of said City and County and State, and Andrew S. Grant of the same place, each personally known to me to be the persons whose names are subscribed to, and who executed the within instrument, and they acknowledge to me that they executed the same.

In witness whereof, I have hereunto set my hand, and affixed my Official Seal, at my office, in the City and County of San Francisco, the day and year in this certificate first above written.

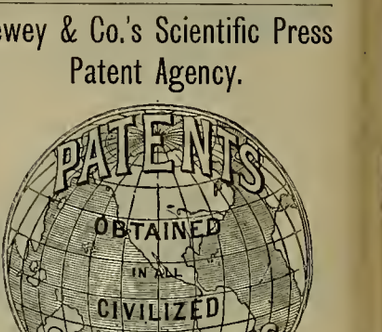
[NOTARIAL SEAL.] GEO. T. KNOX, Notary Public.

EVERETTE'S MINING OFFICE.

Pioneer Mining Office of the Northwest Coast.

Having the largest permanent brick assay furnaces, chemical laboratory and mining office on the Northwest Coast, with a collection of about 4000 samples of the ores of Alaska, British Columbia, Oregon and the Northwest Territories; and having made personal examinations of nearly every mining camp on the Pacific Slope, from California to Alaska, I am prepared to do any class of legitimate and honest mining work, such as EXAMINING, ENGINEERING, SAMPLING AND REPORTING ON THE VALUE OF ALL MINERAL, COAL AND FIRE-CLAY PROPERTIES, BUILDING STONES, EARTHS, ASSAYS AND ANALYSIS OF ORES, WATERS, CHECK SAMPLES OF ORE, PULPS, "ORGANIC ANALYSIS" WORK, and in fact any work connected with the office of a first-class mining geologist and chemist. Any information mining men may desire to know relative to the MINERAL OR COAL RESOURCES of the entire Pacific Northwest will be honestly given. Address **Dr. Willis E. Everette**, Consulting Mining Geologist and Chemist, 1318 E Street, Tacoma, Wash.

Dewey & Co.'s Scientific Press Patent Agency.



OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

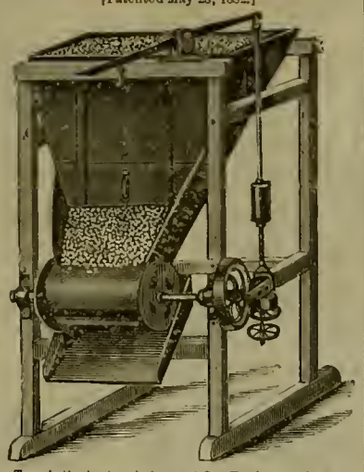
COAL MINES OF THE WESTERN COAST.
A few copies of this work, the only one ever published treating of Pacific Coast Coal Mining, have been obtained, and are for sale at this office for $2.50 per copy. It was written by W. A. Goodyear, Mining and Civil Engineer, formerly of the California State Geological Survey.

THE ROLLER ORE FEEDER
[Patented May 28, 1882.]



This is the best and cheapest Ore Feeder now in use.
It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.
In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

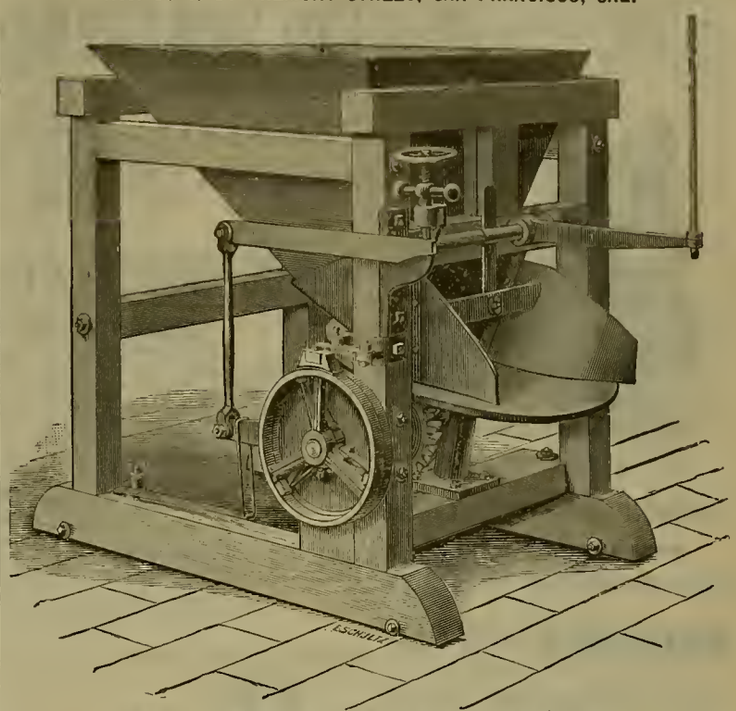
GRANGER'S ROLLER STAMP MILL
Beats them all. Works dry ores. Makes even granulation. No dead work, hence minimum wear.
A. P. GRANGER, Denver, Colo.

GRANGER'S DRY ORE SEPARATOR
The very best. Uses no water. No freezing up. Saves hauling waste. Saves high percentage. Send for circulars.
A. P. GRANGER, Denver, Colo.

"A RIGID EARTH," being devoted to Geology as Applied to Mining. By STEPHEN BARTON. In this work the author addresses himself to intelligent Miners who have, to some extent at least, familiarized themselves with the accepted theories of elementary geology. He has ground together numerous observed facts tending to disprove the igneous theory, and to establish the proposition that below the action and influence of the atmosphere all fissures grow narrower with depth—that metal-bearing veins are produced by causes acting near the surface; and that the realm of successful mining never penetrates the earth one mile. PRICE $2.00. J. O. WARD, General Agent, 64 Main Street, Visalia.

—THE—
JOSHUA HENDY MACHINE WORKS,
Nos. 39 to 51 FREMONT STREET, SAN FRANCISCO, CAL.



"HENDY" IMPROVED "CHALLENGE" ORE FEEDER.

The best form of Feeder ever devised, and pronounced by reputable mining men to be far superior to any form of "Roller" Feeder manufactured. We refer to the following gentlemen who have furnished us with testimonial letters to the above effect, which can be seen at our office, viz.:

N. W. CROCKER, Supt. Bunker Hill Gold Mining Co., Amador City, Cal.
W. G. ROBERTS, Greenwood, El Dorado Co., Cal.
D. C. WICKHAM, Taylor Mine, Greenwood, Cal.
J. R. TREGLOAN, Supt. South Spring Hill Gold Mining Co., Amador City, Cal.

WE ARE MANUFACTURERS OF THE
'CHALLENGE," STANFORD," "TULLOCK," & "ROLLER" FEEDERS,
And will furnish descriptive Catalogues and quote prices upon application.

The Safest and Strongest High Explosives in the Market.
GIANT POWDER or DYNAMITE,
Of Different Strengths as Required.
NOBEL'S EXPLOSIVE GELATINE," which contains **94 per cent of Nitro-Glycerine,** and **GELATINE-DYNAMITE, Stronger than Dynamite** and even Safer in Handling.
JUDSON POWDER IMPROVED.
FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.
BANDMANN, NIELSEN & CO.,
CAPS and FUSE for Sale. GENERAL AGENTS, SAN FRANCISCO CAL.

COMMON SENSE
PULVERIZER AND CONCENTRATOR.
PATENTED DECEMBER 31, 1889.
This is the most practical machine yet discovered for working Gravel, Cement, Clay, etc. By its use you avoid crushing the rocks, which are washed clean, while at the same time it pulverizes the cement and clay and saves the gold, though fine as flour.
You do away with a long line of sluice-boxes and only use about six inches of water. One hundred tons or more of gravel can be worked every twenty-four hours.
It consists of an iron cylinder about sixteen feet long, set horizontal, in which a shaft filled with projecting teeth or arms set in spiral form is made to revolve from 150 to 250 revolutions per minute. At the discharge end of the cylinder there is a screen, where the coarse rock is thrown out, while the finer material runs into another cylinder, built in the same way, about twelve feet long, the shaft of which is made to revolve double the speed of the first one, thereby breaking up the finer pieces of cement or clay and freeing the gold, which is deposited in the bottom of the cylinder.
Satisfactory recommendations furnished from practical miners who have seen the machine in actual use. Address

GRASS VALLEY, NEVADA CO., CAL., Nov. 10, 1885.

Joshua Hendy Machine Works, 39 to 51 Fremont St., S. F., Cal.:

GENTLEMEN—I am pleased to state, in reference to the "Triumph" Ore Concentrators, that four (4) of them were placed in the mill of the Original Empire Mill and Mining Company in April, 1884, and a thorough test made of their practical operation; and their efficiency having been demonstrated, four (4) more were subsequently introduced as the complement of the Twenty (20) Stamp Mill, and the eight (8) have been and are now running with entirely satisfactory results.

At the Ten (10) Stamp Mill of the North Star Mining Company, under my supervision, four (4) are also in successful operation, and from my observation of their practical workings, I am convinced that this form of Concentrators is the equal, if not superior to any other style of Vanners or concentrating devices. DAVID McKAY, JR.,
[Signed] Sup't North Star and Original Empire Mining Co.

N. B. When the stamping capacity of the two above named mills was increased, more "Triumph" Concentrators were purchased, and twenty-eight (28) are now in constant successful operation.

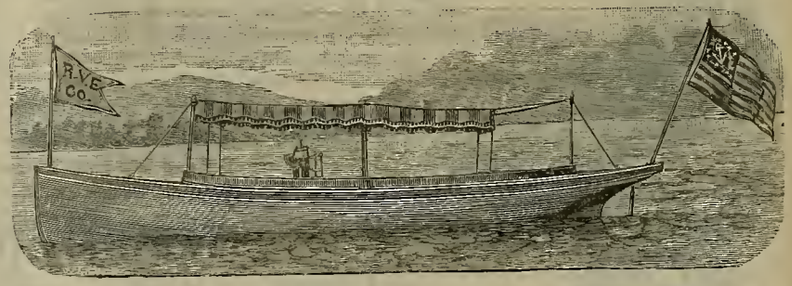
GEORGE HAAS, 824 Market St., Phelan Building, }
SAN FRANCISCO, Feb. 21, 1890. }

REGAN VAPOR ENGINE CO.—Gentlemen: The 2 H. P. Engine you put up in our factory last November, has given satisfaction beyond my expectations. It do s my work better than than those two Electric Motors did, with scarcely any expense for gas. I paid the Motor Company $25 per month for power, while the Vapor Engine has cost me but $2 per month so far. But, be it understood, I have not used the Engine as much as in summer, but the cost of motor would have been all the same, making a saving of $69 in three months. I am satisfied the Engine will pay for itself in less than two years. I use it for freezing cream, run three fans, cocoanut grater, etc.
Yours truly, GEO. HAAS.



Regan Vapor Launches

The uses for small steamboats and launches are innumerable; they are convenient and serviceable for transportation, and are a source of pleasure for those who are fond of sailing. But many have been deterred from purchasing such boats, because of the trouble and inconvenience of using coal, and the necessity of obtaining a Government license, engineer, etc. Our motor does away with these objections. The small space taken up by our engine in the boat gives more room; the boat will seat twice as many persons as one the same size fitted up with a steam engine. It takes only two minutes to get under headway, and can be stopped when running at full speed within the length of the boat, the reverse motion being instantaneous and effective. We carry in stock six regular sizes of hulls, from 18 to 33 feet in length, our models being the best that can be obtained, and built in the strongest and most substantial manner by Thos. Kane & Co., Racine, Wis.

New Field Locomotive.

It looks as if we were about to make important changes in our mechanical appliances and methods of farming in this State. The field locomotive, pulling its quota of 10, 12 or more plows, and turning over 25, 30, and even 40 acres per day, at a cost of about 50 cents per acre, is becoming too common to excite special attention. Not only is the plowing done by steam, but the harvesting, and, in some cases, the hauling as well.

Just what a saving of one-half or so in the cost of raising wheat means to the industries of this State is something hard to realize.

Among the latest machines for this purpose is the new field locomotive of Jacob Price, illustrated on this page. It is said that this machine pulled, near San Leandro, one day last week, an outfit of twelve 11-inch plows in a dry, adobe soil, traveling at the rate of over four miles per hour in doing so, and maintaining the steam pressure at 130 pounds, without difficulty.

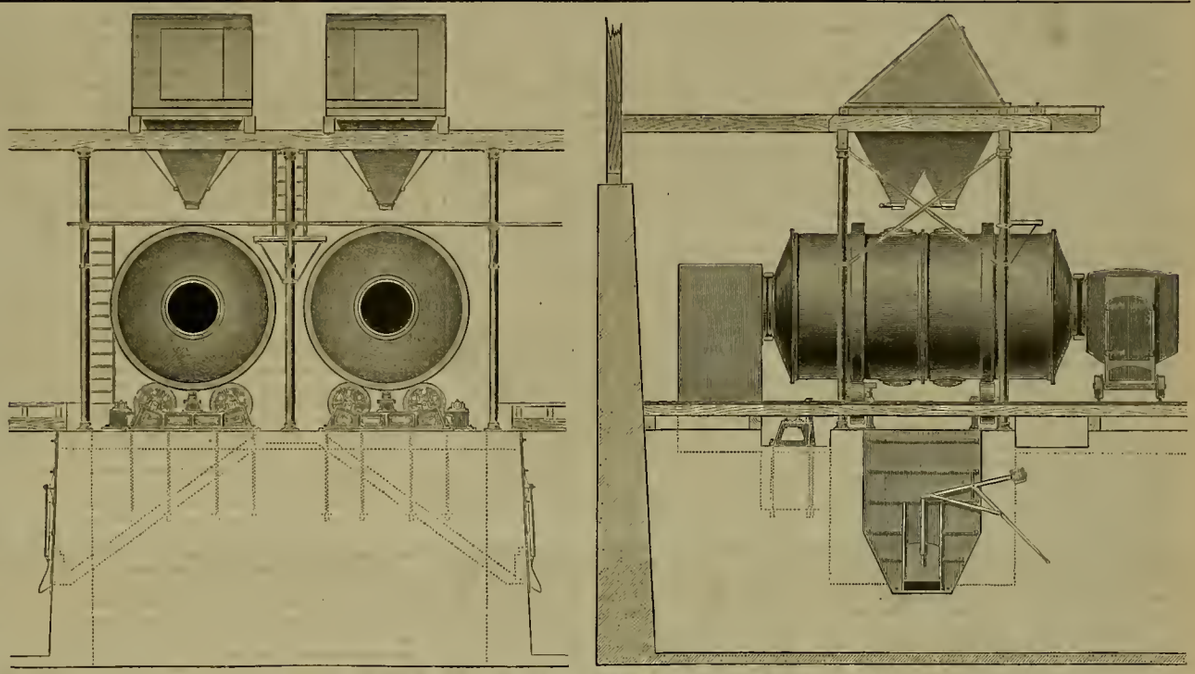
A number of farmers were present, who agreed that to pull one of the 12 plows in that soil, hard as it was, would have required at least four horses, or 48 for the 12. As the locomotive pulled them at fully twice the speed of horses, it follows that the machine was actually doing the work of nearly 100 horses, a thing that seems incredible for a machine weighing less than nine tons.

The exhibition was made to satisfy the agent of a bank in this city, who had been examining various steam-plowing outfits with a view to purchasing one, to be used on lands owned by the bank. At the conclusion of the trial, the sale was made and a portion of the purchase-money paid.

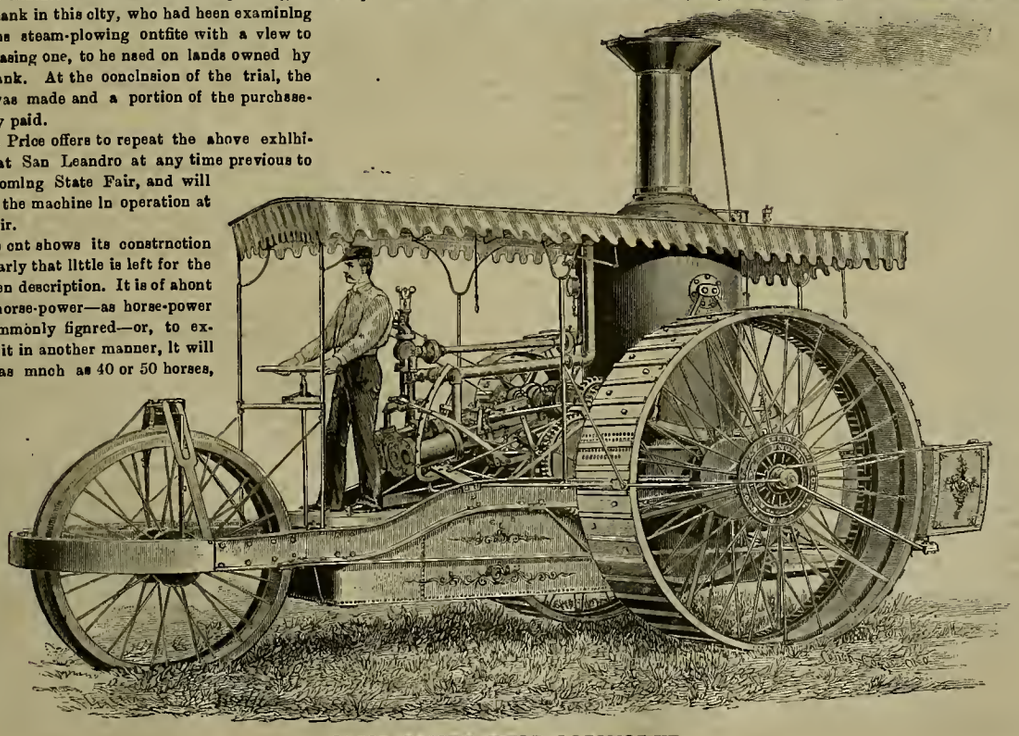
Mr. Price offers to repeat the above exhibition at San Leandro at any time previous to the coming State Fair, and will have the machine in operation at the fair.

The cut shows its construction so clearly that little is left for the written description. It is of about 100 horse-power—as horse-power is commonly figured—or, to express it in another manner, it will pull as much as 40 or 50 horses, besides propelling itself. Its weight is only 8½ tons. The carrying wheels are about eight feet high and 26 inches wide. The steering wheel is five feet high and 14 inches wide. The boiler is an enlarged fire-engine boiler of the most approved type, and is made strong enough to carry 200 pounds working pressure with safety. Its fire surface is 200 feet and its other heating surface (flues) 200 more, making a total heating surface of 400 feet. The main gears are steel rollers working on oiled steel pins, and the remainder are made from metal patterns cut by the celebrated gear-makers, Brown & Sharp, of Providence, Rhode Island.

The entire machine is mounted on long, easy, elliptic springs, in a manner that utterly obviates any interference with the working of the gears, a result, according to Mr. Price, never accomplished before. The machine has twin engines, piston valves and link motion. It is adapted for plowing, running combined harvesters, freighting with wagons, hauling saw logs, or pulling of almost any kind, and is suitable for any stationary work such as running thrashing machines, sawmills, etc. It is made in two sizes, the larger one being as shown and described above and the smaller of about half its weight and power. Its appearance, as is evident from the cut, is much in its favor, being very compact and neat as well as convenient in the matter of throttle and reversing levers and steering gear. It is almost wholly of forged steel, and was made at the works of the J. I. Case Thrashing Machine Company, Racine, Wisconsin, by Jacob Price of San Leandro, California, and also of Racine, Wisconsin.



THE IMPROVED BRUCKNER ORE-ROASTING CYLINDER—See page 142.



JACOB PRICE'S FIELD LOCOMOTIVE.

Mechanics' Fair.—Applications for space at the coming Mechanics' Fair are being daily made. A double engine and large vacuum pump have been loaned by the California-street Railway Co., and will be placed on exhibition by C. H. Evans & Co., builders. Foundations for two large additional engines are now being constructed. Forty feet square has been applied for in which to manufacture rubber goods. The directors have asked A. S. Hallidie to place on exhibition the original models, material and appliances appertaining to the cable railway system, and also statistics of the application and growth of the system.

The suit of Charles W. Hendel to recover $15,890 from B. F. Baker, involving the Pioneer Mining Company, has been transferred for trial from Sierra county to Alameda county.

George B. Walker, a California pioneer and well known as a promoter of mines, died this week in New York.

CORRESPONDENCE.

We admit, unindorsed, opinions of correspondents.—EDS.

The Anaconda Mine.

Description of an Immense Property.

EDITORS PRESS:—This now justly celebrated copper mine was located by Hickey Bros. in 1876. Some time after its location they gave Chas. X. Larrabie one-half to sink a shaft 50 feet on the vein. Then afterward Marcus Daly acquired one-third of the mine for doing some further development, and it did not attract much attention for several years. In November, 1880, Mr. Daly bonded the other two interests for $10,000 each, and went to work to thoroughly satisfy himself as to the worth of the mine, which thus far had been considered a silver prospect, and I have been informed that after the property was merged into the Anaconda Co., the first plant that was ordered for the property by that company was a complete dry-crushing silver-mill; but before they had it placed, the sinking ran into copper ore and they abandoned the silver idea.

The large three-compartment shaft was sunk to the 1000 foot level and stations out; crosscuts and levels run at each 100 feet, and a locality for a large reduction works was sought. The nearest point that was feasible was selected on Warm Springs creek, 22 miles southwest of Butte, and what was at that time considered a monster plant was placed with a capacity for handling 1200 tons daily. It was but a short time until the development of the mine showed such enormous ore reserves that they decided to increase their capacity to sufficient size to work 3000 tons daily. This was all decided and the preliminary work begun before the Secretan and his French syndicate began the boiling of the price of copper, which was then below 10 cents—a proof that the price of the red metal cut no figure with the capitalists who are behind the enterprise.

Their immense new smelter was about completed when a fire took place and the whole plant was consumed. What would have swamped an ordinary mining company was not considered by these gentlemen. They at once began to clear away the debris and place orders for the iron, and the smelter at Carroll is again in complete running order, and is now fire-proof, being wholly constructed of iron.

The old or upper works are now being gradually torn out and rebuilt of iron. When they are completed, the Anaconda will have the most extensive and the best constructed reduction works in the world. The question of cost has never been considered. When any machinery is placed, the only query is, Will it do the work, and will it give us better results at a lower cost of handling our immense output? If it will do this, they want it, whatever it may be, and in carload lots.

Large Operations.

The magnitude of this company's operations can scarcely be conceived by parties who are unfamiliar with large workings. Their shipments of copper during the past year amounted to over 30,000 tons. The estimate of the amount of silver in this is nearly 2 000,000 ounces, and the appreciated prices of this year will largely swell the gross product of the company.

The company have expended in development, purchasing mines and in their plant since November, 1880, to Jan. 1, 1890, over $24 000,000. It almost takes a man's breath away to think of the amount, but when the fact is considered that they use 75,000 tons of coal and a like number of cords of wood and 15,000,000 feet of lumber during a year, and that the railroads receive from the Anaconda Company in the vicinity of $1,000,000, the sum total is not so surprising.

Mine Development.

The Anaconda and St. Lawrence have not yet recovered their places as ore-producers since the fire of November, 1889, but by Sept. 1st everything will be in shipshape order. During all the time since the fire occurred they have kept their shipments up to about 1800 tons daily by increasing the output of the Chambers Syndicate mines, consisting of the Wake-up Jim, Wild Bill, Modoc, High Ore, Bell, Mountain Consolidated and Buffalo Diamond. These have all been developed from 500 to 1000 feet in depth and stations cut with crosscuts to the leads, levels run, man-holes put in, and everything is shaped up for extraction of ore whenever wanted in quantities to suit the requirements of their reduction facilities.

The Town Built Up

In the vicinity of the smelting works is a lively city of nearly 7000 people and sports all the modern improvements of the day—fine water works, lighted by electric lights, and the finest hotel building in Montana. There is nothing to compare with it between St. Paul and Portland.

The General Manager

And prime mover in this gigantic enterprise is Marcus Daly, who came into Butte with the second emigration or rather during the quartz excitement. For a time he operated in the interest of the Walker Bros., and during this time opened up the Alice mine and built the plant now crushing ore on that property. Becoming dissatisfied, he sold his stock in that company, resigned his position as superintendent and struck out to find a better thing as the saying goes, and he has certainly been successful in the superlative degree. He has looked after the company's many interests since that time in a most satisfactory manner. He has found time to improve an elegant home in Bitter Root valley, and has stocked his ranch with some of the finest horses in the land. Mr. Daly is certainly possessed of wonderful executive ability to be able to direct the development of the large group of mines and build the enormous plant now in operation by the company. It is fair to presume that a portion of his success may be attributed to his discernment in selecting his lieutenants, as but few changes occur in his official family. Mike Carroll went to work with him on the shaft that was sunk under the bond from Hickey & Larrabie, and he is still mining superintendent, and there are not many nooks and corners in the properties that Carroll is not familiar with.

The company has directly in its employ at the mines and smelters about 3000 men, and indirectly nearly as many more gain a livelihood, making it a heavy contributor to the general prosperity of the new State of Montana.

The Future Development

Of the properties is full of possibilities, but of ore reserves that are already open and capable of being measured up, they have many years' work in sight. The lead on the 1000-foot level is 21 sets of timber wide, all of which is mined and sent to the works at Anaconda. This will show what a mountain of ore they have to draw upon for their future supplies.

Rumors have been circulated at times during the past 12 months that an English syndicate was negotiating for the Anaconda properties, but no evidence can be obtained on the subject that can be considered authentic. The work of improving and completing their operations is carried on with the same vim and activity that has characterized their work from the beginning, and, to the general observer, would give the idea that they were preparing to produce copper and silver by the carload for the next century.

The management of the Anaconda Company are always on the alert for new properties, and when a new camp starts up, either in Montana or Idaho, they are sure to have representatives on the ground to look the field over, and if it promises well for the future, they will have bonds on a number of the prospects and always push the prospecting of a new camp along rapidly. They have ample means to put in machinery, and arrive at results in a few months that the original locators might struggle with for years and then have to forfeit their rights. They frequently have differences and troubles with the railroads on the matter of keeping up their supplies, and at one time it was thought that company would build and operate their own road from the mines to the reduction works. When the railroads see that they are taking chances of losing their best patron, they always come to time, and all goes serene for a time. The visitor who passes through Butte without taking a drive around and seeing the number of properties of the Anaconda Co., and the magnitude of their operations, and their concentrating, milling and smelting plant, has not seen the most interesting portion of a trip to Butte.

It is particularly unfortunate that it is necessary to keep the works so closely guarded, but it is, I presume, one of the necessities when such extensive operations are carried on to have none on the grounds except those who have business there, as persons going to and fro indiscriminately cause employes to neglect their duties while asking questions, and their only protection is to exclude them without fear or favor.

Refining Works.

The company has secured title to a large quantity of land at Three Forks, 70 miles east of Butte, with unlimited water-power, and it is said to be their intention to add a very extensive refining works, which, of course, will make a heavy reduction in their freight, as they ship their matte at about 65 per cent now, and the item of 35 per cent of a yearly output of over 30,000 tons is a large item of expense, and if they can refine it here, it will be another pay-roll in the interest of Montana. Each addition of this kind means continued prosperity assured.

The wants of the company in the way of general supplies for current use at the mines and works are purchased and distributed by the Butte Trading Company, a corporation within the Anaconda Co. Their volume of trade must be enormous, judging from the number of carloads of goods unloaded at their warerooms. The Montana Union switches are run into the hoisting works in order to deliver lumber and other heavy materials convenient for handling, and many thousand feet of lumber are kept on hand in reserve, in case of the railroad being blockaded or stopped from other causes. This description of the Anaconda mine and plant is rambling, but will serve to give the readers of the PRESS some idea of its vastness. The company being a close corporation, the best facilities are not furnished for writing the mine up in detail, and your correspondent has had to depend on many different sources for what information has been furnished. R. G. H.

Butte, Montana.

Copper in British Columbia.

EDITORS PRESS:—Prospecting work on the Victoria Copper Mining Claim has been in progress the last two months. This claim was located in 1889 by parties from Spokane Falls, Washington. The lode is six inches to three feet in width. The solid copper ore lays in deposits or chutes. The average assay is 60 per cent copper per ton; selected assay 65 to 75 per cent; also carries some gold and silver. The formations are syenite and granite. A shaft is being sunk on the ore chute, and at present depth the chute is increasing in size and quality of ore. The lode dips into the mountain at an angle of 45 degrees, and runs north and south. Solid pieces of copper weighing 100 pounds have been taken out near the surface. The intentions are to develop the claim thoroughly. C. BECKINGER.

South Fork of the Similkameen River, B. C.

Clarifying Water from Streams and Ditches.

EDITORS PRESS:—In a recent number of the PRESS the difficulties encountered in securing pure water, and the methods employed by the leading water companies, was ably written up and illustrated. This same difficulty was met and overcome by the miners of '49, and their experience may help to solve the problem of how to obtain pure water. The miner used the water in the mountain section where storms were frequent and severe; in consequence the wash from the hillsides and gulches soon filled his reservoirs and ditches. As a rule he was compelled to use water that carried all the tailings from a mine farther up the stream, and this had to be disposed of before it could be turned into another ditch. The '49er proved himself equal to the emergency in this as in everything else. Dams built across the ravines impounded the wash coming down from above. Headgates placed at different levels allowed the drawing off of clear water from the reservoirs. Where the sand filled into the ditches badly a slot was cut across the flume and a 2x4 placed back of it. Through this slot the sand dropped, and thus left the ditch free from accumulating sands where the mud or slickens was held in solution. Slum-boxes were built at the side of the ditch. The water, by means of gates, was turned into these slum-boxes, and at the lower end of the box turned out by another gate into the ditch. These boxes were about three feet lower than the bed of the ditch, and so acted as settling tanks. When nearly full the upper gate, which turned the water into the slum-box, was taken out of the flume and placed across the entrance to the slum-box; then a gate at the lower side of the slum box was opened and the slum either shoveled out or a stream of water was turned in sufficient to wash it out. These slum-boxes could be built in succession and the water settled until it was as clear as desired.

When in Dakota, in '80, the superintendent of the Homestake mine used the water appropriated by another, and although he restored it to the same stream, was sued for damages for fouling the water. He put in a series of slum-boxes, and when the case came up for trial, placed on exhibition a bottle of water taken from the stream at the point where his ditch diverted the water, and another bottle of water from the stream below where he discharged it from his slum-boxes. The court found that the water had been purified instead of befouled, as it was cleaner after than before using.

Murphys, Cal. E. H. SCHAEFFLE.

THE OPHIR.—The Ophir Mining Company shipped by the Virginia & Truckee railroad express train through Wells, Fargo & Co. last evening six bars of bullion valued at about $25,000, without the discount on silver deducted. Gold predominated over the white metal in the bars. This bullion is the returns from 883 tons and 1630 pounds of ore shipped to the Morgan mill and extracted from the Ophir mine in advancing the upraise above the 1465 level and following the ore developed there north and south, and in prosecuting explorations on the 1465 level. The returns show an average bullion yield of nearly $29 per ton. None of the ore developed in the winze below the 1300 level has yet been shipped; that extracted in exploring the extent of the development is temporarily stored on the 1400 level of the mine. The Ophir Mining Company since its incorporation has disbursed to shareholders $1 595,800 in dividends. The last paid was $1 per share, declared Jan. 12, 1880, out of ore extracted from the Hardy vein. The assessments levied by the company to date aggregate $4.210,640. The financial statement filed Aug. 1, 1890, showed a balance of $23 505.11 in the company's treasury on that date, which, added to the bullion shipment made last evening, makes a total of about $45,000 in the treasury, with the discount on silver deducted. Should further explorations demonstrate that the new ore development in the mine is as valuable as it promises to prove, another dividend at an early date is among the probabilities.—*Virginia Chronicle.*

RIVER MINING.—Says the Grass Valley *Tidings:* A young man who is engaged in river mining in the Yuba, working with a rocker, has averaged $6 35 in gold per day. An expert Indian, also with a rocker, has taken out as high as $16 a day. Next summer will see very active work in this line, and some big cleanups will be heard of. The amount of gold in the Yuba and its tributaries, washed down from the hydraulic mines, cannot be estimated, but it is known to be very large.

San Bernardino County.

Its Mineral and Other Resources.

NUMBER VIII.

[Written for the PRESS by JAMES H. CROSSMAN.]

Other Springs

In addition to those springs mentioned in my article of last week, the following are important as being situated on traveled routes or trails leading to the several mining districts. These are all in San Bernardino meridian except those otherwise indicated:

Black's Ranch Spring, Tp. 11 N., R. 3 W.
Dry Lake Spring, Tp. 11 N., R. 4 W.
Cottonwood Springs, situated in Tp. 9 N., R. 15 E.
Bonanza Springs, situated in Tp. 7 N., R. 16 E.
Chimehuevis Valley, on which occur several springs, the principal one of which supplies West's ranch. Its location is Tps. 4 and 5 N., R. 22 and 23 E.
Warren's Springs, Tp. 9 N., R. 3 E.
Warm Springs, near Newbury Station, Tp. 9 N., R. 15 E.
Willow Springs, Tp. 8 N., R. 12 E.
Surprise Springs, Tp. 2 N., R. 7 E.
Seven Palms, Tp. 1 N., R. 9 and 10 E.
Rabbit Springs, Tp. 5 N., R. 13 E.
Crystal Salt Springs, Tp. 5 N., R. 21 and 22 E.
Soda Lake Springs, Tp. 12 N., R. 8 E.
Borax Lake Springs, (Searles), Tp. 19 N., R. 7 W., M. D. M.
Hedden Springs, Tp. 18 N., R. 1 E.
Lone Willow Springs, Tp. 18 N., R. 46 E., M. D. M.
Salt Springs, Tp. 17 N., R. 8 E.
Leach's Point and Springs, Tp. 17 N., R. 3 E.
Granite Springs, Tp. 14 N., R. 42 E., M. D. M.
Kingston Spring, south end of Kingstoo Spring Mountain Tp. 21 N., R. 10 E.
Boiling Springs, on east border Dry Lakes, Tp. 20 N., R. 7 E.
Cronise Lake Springs, Tp. 13 N., R. 7 E.
Furnace Creek Spring, its head forms the supply for Colemao Borax Works and Refinery, Tp. 26 N., R. 4 E.
Hidden Springs, Tp. 18 N., R. 1 E.
Bitter Springs, Tp. 13 N., R. 5 E.,
Marl Springs, Tp. 12 N., R. 13 E.
Crossman Springs, Tp. 17 N., R. 15 E.
Rock Springs, Tp. 11 N., R. 16 E.
Rabbit Springs, Tp. 4 N., R. 1 E.
Ludlow Springs, Tp. 9 N., R. 8 E.
Cove Springs, Tp. 8 N., R. 13 E.
Palm Spring, Tp. 1 S., R. 8 E
Brown's Well, Tp. 5 S., R. 16 E.
Chuchawalla Springs, Tp. 7 S., R. 17 E.
Mule Spring, Tp. 7 S., R. 20 E.

This list of wells and springs, and their localities, though not of interest to the general reader, is of the utmost importance to the desert traveler.

Artesian, Pump and Curb Wells.

At the Amargosa Works in the Death Valley basin, a well has been sunk to a depth of 528 feet, using a seven-inch pipe. The discharge is 20,000 gallons in 22 hours, throwing the water above the curb 20 feet.

Four miles south from this point is a well sunk to a depth of 40 feet. From its bottom, when bored 40 feet farther, a flow of pure water came in so strong that the workmen were unable to put in pipe, and the water having no check or restraint, flows to the surface and overflows. The Calico dry lake, situated four miles north of Daggett, contains six wells on its northerly shore, from one-fourth to two miles apart, which average 100 feet deep and in which the water rises to a hight of ten feet in inexhaustible quantities. The water is pure and soft. The wells on the north shore of Lava Bed mountain, in a dry lake 35 miles east of Daggett, average 60 feet in depth. Water good and supply inexhaustible.

The wells of the Ludlow dry lake, eight miles north of Ludlow station, on the north shore, 80 feet deep, furnish an abundant supply of good water.

On the north shore of the Rabbit Spring dry lake, 18 miles northeast of Victor, a well furnishes an abundant supply of pure water; the same at Warrens and at Dry Lake, 40 miles east of Victor. Two wells over in New York valley, 35 miles north of Providence, at a depth of 14 feet; two at Black Ranch, 20 miles northwest of Barstow; one at Galena district, 30 feet deep, nine miles west of Oro Grande; Naelans well sink on the south shore of Death valley, three miles south of Saratoga springs; one well sunk five feet at Valley Wells, 37 miles southeast of Soda lake, all furnish an abundant supply. The above wells were all sunk on non-alkali soil. I find that the wells sunk on soil covered with alkali show the same result. For instance, at Soda lake, Warm Springs, Dry lake, etc., the water of all of the wells is found near the surface. At a proper depth there is no doubt but what artesian water could be obtained. That the soil possesses great qualities of fertility is demonstrated by the rank growth of several varieties of grasses and wild flowers whenever there is an unusual wet season.

Storage Reservoirs

We have already made reference to and described in part the immense storage systems that become necessary in order to render otherwise arid lands south of the San Bernardino range susceptible of cultivation. Suffice it to say, there are many available reservoir sites in the valley that have not as yet been utilized. The writer noticed one in particular 1½ miles east of Lyth creek in Sections 4 and 9, Tp. 2, N. R., and 4 and 9 N., R. 5 W., where a flat known as Lycem occurs consisting of 160

acres. At its outlnt a dam 600 feet long by 75 fent in hight, with a hasn of 150 feet, costing not to exoned $15,000, would form a reservoir which, when filled from the surplns water of Lyth creek, would contain many millien gallons of watnr. Its mean depth would be 40 fent.

Another catchment hasin in the vicinity could hn filled from thn samn sourcn. The dam would hn of the following proportions: 200 feet long from hill to hill and 100 feet high. This would flood an area of three quarters of a mile in length by 300 feet in width hy 40 feet deep sufficient to irrigate 3000 acres. One miners' inch of watnr is estimated to hn enough to irrigate six acres of land. Many of the ditches in this region arn oement linnd, hottom side and permitting an even flow of the water.

Water in ditches that are not cement-lined loses 50 per cent in eight months, while in cement lined ditchen thn loss is only hy nvaporation—not exceeding ten per cent.

The Santa Ana ditch is of this class. Its length is six miles. The dimensions are 4 hy 6 by 3 fnet deep, slope 55 degrees, cement lined.

Desert Regions.

Northb of the range, reservoir sites are also nhundant. There arn many places in tbis region where large areas can be ntilized by short and inexpensive dams conserving and holding for man's nse extensive hodies of water for irrigation purposes. This, with the resultant vegetation (trees and shrubbery), wonld assist Nature in reducing the temperature of the atmosphere many degrees.

Artesian Wells.

Wn have alrnady shown that artesian water in immense quantities oan he obtained in almost any portion of the desert region. Subterranean channels filled with pnre, living water exist heyond a shadow of doubt at greater or lesser depths hnlnw the earth's crnst, which serves as a blanket, proteoting it from the desiccating effects and powerful rays of the sun. These ohannels form nnderground rivers constantly receiving fresh snpplies from tributary streams and sources, the combined watere of which form the artesian belt of this region. In the immense superficial area of 14,340 square miles of territory that comprises the desert region, the snhterranean waters are not confined to one channel, hut there are many large branchee or forks to the main arterial stream, which in thumselves form rivers of no small proportions. Toe evaporating rays of tbe sun, though powerful, are not sufficient to take up hut a very small perocntage of the water that falls from the heavens even in an ordinary season, much less the unusual preciptation of the past year.

C. H. Fairchild, railroad agent of the Southern Pacific railroad, at Mojave, on the desert, who keeps a rain-gauge, furnishes the following date, which I reproduce in connection for illustration:

Precipitation, July 1, 1889, to Dec. 15, 1889	6 52
" Dec. 15, 1889, to Jan. 30, 1890..... .	5 95
Season.....	12,47

This sea of water was not evaporated by the rays of the sun. The precinitation from Dec. 15 to Jan 30, 1890, was 5.95 feet. Thermometrical readings during that time showed a mean of 46 degrees Fahrenheit. Ice was often formed, the thermometer renging from 30 to 62 degrees. What hecame of this water? It did not stand in pools, and had no surface-flow discharging into any visible stream that debouched into tbe ocean, hnt was absorbed by the sands of the desert passing into snhterranean channels soon after falling, en route to the Father of Waters. Let the reader reflect a moment and use a few figures, and he will find that the down-pour of the aqneous fluid during that period, if conserved on the surface would form an inland lake, covering the whole desert regions, of sufficient depth to float a light-draft steamer.

Underground Rivers.

Tbat waters of nnderground rivers, by the force of powerful hydrostatic pressure, find their outlet in the ocean through snhterranean channels which form hermetically sealed tuher, is a well-attested fact. In the Atlantic ocean, off St. Augustine, Florida, immense springs of pure, fresh water spont up from amid the salt water at conciderable distances from the shore. This phenomenon has been noted in many other places. Water, like other fluids, will find its level. It is these snhterranean streams that form artesian belts. The desert regions of San Bernardino county contain a snhterranean river of thie character of immense proportions. Theee watere have been stored for man's nee and can he brought to the surface hy artesian wells, serving to fertilize and make productive more than four milllon acres of rich land.

I am well aware that this immenee scheme cannot he accomplished by individual enterprise. No individual or combination of individuals have the requisite capital. It requires Congressional action and Government aid.

Senator Wm. M. Stewart and other farseeing statesmen are enlisted in thie cause and moving in the right direction. They are now advocating thie measure in the halle of Congress.

In thie article I have made hnt little reference to the extensive and elaborate system of storage reservoirs, artesian belt with its artesian wells, or other sources of water supply that lie south of the San Bernardino range of mountaine, as I have made special reference to them in a previous article.

(To be Continued.)

Vegetable Fibers.

Shall we ever have the extraction of vegetable fiber by machinery brought to the point of success which will justify a farmer in growing a crop of ramie or other fiber plant? It is interesting to describe how well such plants thrive in this State and what vast sums the civilized world pays the barbaric producer, who works ont the product by hand or with rude appliances, and is content with a few cents a day as wages. It is interesting, too, to read of the many fiber extractors and extracting processes which show fine samples and then offer the farmer a machine or a right to use a process for so many hundred or so many thousand dollars. Such offers do not constitute a practicable basis upon which to urge the production of these fibers in this country. The farmer cannot grow a crop of the fiber plant and then assume the labor and expense of manufacturing it into merchantable fiber before he can realize for his labor and the use of his land. To make the enterprise available the capitalist must buy the machines or the processes and carry on the extracting concern, contracting with the farmer to take his crude fiber green or dry at so much per ton, delivered at the factory or put aboard the cars or steamer. Just as soon as the proposition assumes this phase the farmers of the United States, or some of the States, will produce as much ramie or other fiber-yielding plant as can he profitably sold.

These facts must be recited because articles are now being published calling attention to the New Zealand flax industry and the large purchase of the prepared fiber in the United States. It is needless to send the seed to this country. The plants have been growing in this State for years and have been distributed nearly all over the State by the university. We know from the reports from widely distant experimenters just about in what districts of the State the plant will succeed. The old plants in Berkeley are seeding freely, and thousands of plants can he had by dividing the old clumps. Now, although all these things are so, who can conscientiously advise a farmer to lumber up his land with New Zealand flax, excepting a few plants which will yield him good material for tying vines, plant bundles, etc.? There is a very important step to he put in between the exhortation and the planting of the crop, and that is the work of the manufacturing capitalist who will provide proper machinery and offer the grower no much a pound, bale or ton for his crop as it comes from the field. Will this ever be done?

There is another fiber material which has been paraded for the last score of years as a possible source of great wealth to this State, and that is the wilderness of so called "wild hemp" on a portion of the Colorado desert. The subject comes forward anew in an article in the Yuma *Sentinel*, from which we quote as follows:

"On both sides of the Colorado river, from Yuma nearly to the Gulf of California, the wild hemp grows spontaneously in great abundance. The growth is perfectly wonderful, the stalk reaching a hight of from 20 to 35 feet, but averaging from 12 to 15 feet.

"This great fiber product or plant covers an area of not less than 50,000 acres, and the lowest estimate ever made places the annual yield of the clean or prepared fiber at 500 pounds per acre, or 25,000,000 pounds, equal to 12,000 tons, or 1250 carloads of ten tons each.

"It is estimated that to cut and prepare this for market will cost three cents per pound, or $750,000. A rate of freight to San Francisco of $7 per ton has been offered. The freight at this rate would amount to $87,500 annually. The harvesting of this amount of hemp would give employment to from 300 to 500 Indians for four or five months each year.

"Most of the fiber grows within two to four miles of the Colorado river, although in places it is found back from ten to 20 miles. It is mainly found among the arroyos or natural canals and lower land, which are overflowed or filled with water in the high waters of the Colorado. It can be cut, and the ontside or woody matter can he removed by passing it through a brake similar to that used in the manufacture of flax. This can he done on the ground where the hemp grows, and thus save the hauling and freight of the extraneous matter, leaving only the fiber to he packed in halee and shipped.

"Using Indian labor, the fiber can he prepared, haled and transported to the Colorado at an expense not to exceed three cents per pound. Even supposing that the freight should reach $10 per ton to San Francisco, this would make the cost of production and delivery 3½ cents per pound.

"The lowest price offered for the prepared fiber delivered in San Francisco is five cents per pound, which leaves a profit of $30 per ton, or $375 000 for the crop per year at the lowest estimate of the yield in the poorest years. This offer has been made for the fiber in 10,000 ton lots, by an English company already engaged in the manufacture of rope, cordage-twine, sacks and matting.

"A wealthy German, engaged in the same industry, after having experimented with the hemp, made an offer of eight cents per pound in 10,000 ton lots, delivered at the month of the Colorado river or in San Francisco, which would leave a profit of $90 per ton, or $1,125,000 per annum. According to these figures, in the good years there would he expended for labor more than $5,000,000, for freight $800,000, with a profit of from $3,750,000 up to $10 000,000 per annum."

This is about the usual wild way in which this fiber industry is generally presented to the public. The tidings comes to the weary mechanic and fills his brains with visions of mechanical triumphs in extraction or to the ears of the poor farmer who longs for some crop which will pay him more money than he can secure hy his present rotation. They all discover, after wasting much time and sometimes money as well, that the proposition is not yet upon a working hasis, and that the articles are written either to win investment in some land scheme or some process scheme. We believe there will yet be profit in fiber production in this country, hut it will not be reached until propositions assume more practicable forms than those in which they now usually appear.

Removing a Bar.

Mr. Joseph McGillivray, formerly of this city hut now a resident of Liverpool, writes as follows to the Liverpool *Journal of Commerce* on a method of improving the harbor bar: I find from a map of the Mersey Docks and Harbor Board of last year's soundings of the part known as the Liverpool har, that the water at low spring tide is only ten feet, and at a point and on a line 300 yards north of and parallel with the line hetween the Bar Lightship and the Formby Lightship; that the distance across the har, from 18 feet depth inside to 27 feet depth outside, is 1800 feet, ontside of which there is ample depth of water and plenty of space to deposit sand from off the har. My plan to deepen thie part is hy assisting the current to scour out a channel through the 1800 feet, bringing it down, at least, to the 18 feet inside. The reason why I take the depth from 18 feet to 27 feet is in order to have grade to assist the current to carry ont the sand. My plan would he to get a set of gang-plows attached to a V-shaped frame, drawn by a towhoat, turning over and entirely loosening the sand, which the last of the ebh tides would carry out and which could he assisted by the use of force-pumps stirring and driving the sand. Also the slickings from the docks could he let down on it from the boppers in quantities, which would materially assist in moving the sand along with it; also hy temporary guides, forming lines on which the current would act. On making a plan of tbe bar, I find from the different depths, and to do tbe work by sections, in order to get as much grade as possible to work on, that from the point section 1, at which the water is 10 feet to the 27 feet, a distance of 900 feet, there is a grade of 17 feet, or 1 foot to 53 1 17; tbet section 2 from 12 feet to 27 feet, distance 1200 feet, grade of 15, equ ling 1 foot to 80 feet; sections 3, from 14 to 27 feet, distance 1500 feet, grade of 15 feet fall, equaling 1 to 115 3 5. No. 4, 18 ft. to 27, distance 1800 ft., 9 ft. grade, equaling 1 to 200. The best result would be got on the last runs of the spring ebbs, as with the least depth of water the greater would he the scour, and the action of the tide outside the har from tbe 27 feet, with the great area, would scatter tbe sand out of the way. My knowledge of the action of water on material in sluices, as well as in rivers, has been derived from a varied experience in the gravel mines of California, and I fully believe that hy following the substance of the above principles, with probable additions which might suggest themselves as the work went on, and with the large quantity of water which comes in and ont of this large basin, that by assisting Nature the bar can not only be materially lowered, hut can with little help be kept deep enough to enable the largest ships to enter at all times, except, perhaps, at extreme low tides, keeping Liverpool as it is—the first port of the world. In conclusion, I may just add that the plant for carrying out tbe scheme above suggested would cost hut little, the services of a tow-hoat being the principal.

SILVER AND PRODUCE VALUES.—The course of silver since the recent active favorable legislation is of interest as related to produce values. In August, 1889, silver was quotable at 92¼c per oz. in New York; now the quotation is $1 19⅞ per oz., an advance of 27⅝ per oz. This means that a miner having an output of 100,000 ozs. would only have received for it last year $92,500, against $119,875 this year, which gives the mine-owners $27,625 more money to spend or loan out. The more money there is, the cheaper the rate of interest and the higher are farm products, and providing the amount of money does not exceed legitimate needs, and has a good basis of value in itself, the more prosperous are our producing interests.

BUTTE COUNTY MINES.—According to the Oroville *Register* there is more activity in mining properties in Butte than for many years past. The sale of the Greek mine and of the old Cape claim was consummated and the money paid on Saturday last to the various owners. The rich returns from the Forbestown mines are attracting capital, and a number of new ledges give fine indications for the future. The Patterson gravel mine, near the famous Carr mine, is paying from $8 to $50 a day for four men. The Carr mine is known to be very rich. The Reese mine, owned by Messrs. Reese, Walker & Smith, is being opened by a tunnel. The amount of gold shipped from this town is not less than $25,000 a month, while the shipments hy private parties, mostly Chinese, are very large.

Southern Nevada.

Mr. James Delavan, mine-census agent, writes to the Virginia *Enterprise* as follows:

One of the greatest improvements made to facilitate the settling and opening up of the western portion of this State was the building of the Carson & Colorado railroad from the Mound house to the State line, in Esmeralda county, and thence on southerly through Owens River valley to Keeler, in Inyo county. The country through which this road passes was almost inaccessible until the railroad was built. Much promising and really valuable mining country lay dormant, or was so remote from sources of supplies that no mining could he carried on at a profit, and capital could not he induced to venture into those remote regions. But now all this has been changed by the construction of the railroad, and since its completion, many new mining districts have been formed, and mines have been opened and worked, whose product adds much to the wealth of the country. This is especially the case in Esmeralda county, Nevada, and Inyo county, California.

Among the number are the mines in Garfield district, lying west of Luning, on the railroad, and the Santa Fe mines, to the east of Luning. There are mines in Marietta district, west of Belleville, from which place ores are shipped to San Francisco, where they are sold to the Selby Reduction Company. There are ores of different characters in the districts; some are free-milling, containing mostly gold. The railroad facilities make it possible to work many mines in Columbus district that otherwise could not he worked at a profit; also in Silver Peak, Lida valley, Montezuma, Palmetto, Sylvania and other districts in the southern part of Esmeralda county.

In Inyo county, Cal., mines are located and are being developed, some of which are quite promising, that would never have been heard of if it had not been for the Carson & Colorado railroad.

The mines at Cerro Gordo, some of which have been large producers, were worked a number of years ago, when all supplies were carted in from Los Angeles, 300 miles distant. All of the silver-lead bullion was sent to Los Angeles for shipment to San Francisco at great expense for transportation. None but the richest mines could he worked at a profit with all the attending expense of transportation of supplies and conveying the bullion to market.

Now all that has been changed hy the building of the Carson & Colorado railroad, and work has been resumed in the mines of this district, with a prospect that they will now he worked at a profit, and many that could not be profitably worked before the building of the road will be made to pay good profit. Cerro Gordo will undoubtedly become a lively camp. The mines in Darwin and other districts below the present terminus of the railroad are also receiving renewed attention since facilities are such that they can now he worked at a profit.

The borax, salt and soda marshes are now producing largely, since the expense of transportation does not consume all the profits, as formerly was the case.

Mines in Hawthorne district have been opened, and have been and are now being worked to quite an extent, creating much business for the town of Hawthorne and the railroad.

Dr. Yates' Publications.

Dr. Lorenzo G. Yates, the well-known scientist of Santa Barbara, is not only an officer of their local Natural History Society and a a corresponding member of the S. F. Microscopical Society, and of the Washington Anthropological Society, hut also claims membership in the American Horticultural Society, American Association of Conchologists, and Geological Society of America; nay more, his scientific associations extend over the sea to the New Zealand Institute, and the Linnæan and Philosophical Societies of London.

Dr. Yates has published a variety of works, which may be ordered of him at Santa Barbara, Cal, as follows:

The California Digest of Masonic Law, 8vo., 236 pp., cloth, 1867. $1.50. Postage extra.

Catalogue of the Ferns of N. America, 8 pp., 1886 25 cts.

Notes on Hawaiian Ferns, 15 pp., 30 cts.

The Ferns of Ceylon, 33 pp., 40 cts.

Catalogue of Minerals in L. G. Yates' Collection, 71 pp., 50 cts.

Catalogue of Fossils in L. G. Yates' Collection, 37 pp., 25 cts.

Catalogue of Indian Relics in L. G. Yates' Collection, 4 pp., 10 cts.

Catalogue of Land and Fresh Water Shells, (Foreign), 40 pp.

Catalogue of Land and Fresh Water Shells (American), 47 pp.

Catalogue of Marine Shells (American), 30 pp.

Catalogue of Marine Shells (Foreign), 51 pp.

Charm Stones ("Indian Plummets") with 4 plates of 31 illustrations. Price on application.

All Known Ferns (just ready), a book of reference, giving the name, habitat and synonyms of all known ferns of the world; with references to other works. Synopsis of Genera and divisions; Bibliography of Ferns: Key to Genera, etc. Bound in cloth. Price, $3.50; postage extra; or with blank pages for notes and additions, $4; postage extra.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

GOVER.—*Ledger*, Aug. 23: They have struck the ledge at the 600-foot level, and have driven 25 feet into the ledge, and as yet the footwall is not in sight in the end of the drift. From what can be learoed it is a high-grade proposition. Stopes have been opeoed up, from which the mill has been kept running. Preparations are being made to open the mine to the 1000-foot level, and sink 300 feet. A large dam is being made at the 400-foot level, as the company are about to put in a pump, which is to be in running order by the 1st of September. It is to be ruo by electricity. As this is the first introduction of electricity for power in this county, it is looked forward to with great interest.

MISCELLANEOUS.—The ten-stamp mill of the McKenzie mine is running steadily, and the indicatioos are said to be favorable for a good paying run. Robert Reed has sold one-quarter interest in the Reed & Askey mine, near Irishtown, to Mr. Chapman of San Francisco. All the incumbrances upon the property have been paid off, and work is to be resumed next week. At the Amador gold mine the working force has been somewhat reduced, for what reason we are unable to explain. Superintendent Darling has been in San Francisco during the past week. The Alpi M. Co. bave concluded to quit the business and divide the small surplus on hand pro rata among those who paid the last assessment. The dividend amounts to .55 of a cent per share. The 10-stamp mill on the Gardiner mine, near Irisbtown, is almost completed. A contract has been eotered ioto for a 20-stamp mill, but 10 stamps will be completed and started before the construction of the rest is entered upon. At the Clinton Peak claim the tuonel has reached a distaoce of 160 feet, 90 feet of which has been tunneled since the resumption of work in the early part of last month. They expect to tap the ledge io about 40 feet more. V. P. Yelmini of Oneida has secured the Griesbach claim in Pioneer district, and is preparing to commence operations thereon.

Butte.

GRAVEL RANGE.—Oroville *Register*, Aug. 21: It is one of the anomalies of Califoroia mining life to note the difficulties that men overcome to obtain the gold from the soil. Here, near Oroville, 100 meo are at work turoing a great river from its bed that the channel may be scraped and cleaned and the gold takeo from the crevices of the bedrock. High upon the mountains known as the Gravel Range, 50 men are at work seeking for gold under difficulties that would appall any one but a California miner. The example of Col. A. P. Frary is a striking one. Last winter was a very severe one and enormous quantities of snow were piled up on the mountains. When the colonel undertook this spring to reacb his mine it was buried beneath deep snowbanks. Nothing daunted, the colonel set his men at work felling great trees and building huge fires to melt the snow off so as to leave the ground bare. He succeeded and has pushed ahead his mining labor with great diligence. He has built some four miles of mouotain grade over which an eight-horse team can travel. He has placed upon the ground a steam boiler weighing 8000 pounds aod a 45-horse power engine. This week he was down after a fine Hooker pump. The sbaft sunk to reach the rich gravel deposits contains so much water that a steam pump is required to keep the flow down. He has 20 men employed and they are busy erecting a boarding-house, engine, blacksmith shop and other needed buildings. He brought in 36,000 feet of lumber from loskip and in a short time will have everything in running order. He is confident that the gravel will run $6 to the car and believes that in one week from the bour he starts up he can take out gravel enough to pay the whole expense of fitting up the mine. The mine is situated on Brown's Ravine some miles above the Chaparral House. In this same neighborhood is the celebrated Carr mine, the mine of Patterson & Co., that of the Shasta boys, the Silva boys, Reece, Walker & Co., Emerson & Co., Geo. Le Rossignal and Bracken & Doyle. Col. Frary expects to start up washing gravel by the 16th of Septemher, and is confident that in a short time rich returns will be made from this mine.

Calaveras.

WEST POINT.—Cor. Calaveras *Chronicle*, Aug. 22: The mining interest of this vicinity has never had a more cheerful outlook than at the present. The old Keltz, or Peasley, mine, under the careful and cautious management of its owner, O. B. Peasley, is developing ioto a magnificent piece of mining property. The ore extracted at present is the best ever produced from this or any other mine in this locality. Mr. Peasley proposes to erect a mill this fall. Henry Trappanier has had a crusbing of quartz from his mine, which is located near the Keltz, which yielded at the rate of $110 per ton. The Lone Star, or Hurley, Mining Co. is producing good-paying quartz, and its mill is kept at work. The Riverside, under the careful management of Mr. Pierson, is developing excellent quartz and large quantities of it. This mine will, without a doubt, prove a good property. The Anoa, owned by Mr. Steger, and the Josephine mine, owned by S. Ruffino and John Soancovich, the one being the exteosion of the other, have been bonded to Mr. Pierson, who will commence work shortly. Messrs. Bennet & Light, who have been prospecting their mine on the North Fork of the Mokelumne river for some time, have struck exceedingly rich rock. The Blazing Star, which has been leased to the miners for three months to give them a chance to get their back pay, is producing rich ore from a five-foot vein. It will not be long before the men will be paid in full from the product of the mine. The owners of the Wide West mine, under the management of George L. Brown, the enterprising and stirring mining man of this section, are getting the mine in shape for work. Mr. Billings, who is owner of the Tom Payne mine, is extracting first-class paying ore. Mr. Watkins, an enterprising gentleman from S. F. who has been engaged in mining in this vicinity for some time, has undertaken to open the Tucker mine. He has a bond of the mine. The Lockwood mine owners intend to sink their main shaft a few hundred feet deeper. The Scorpion, which has been idle for some time, is soon to be reopened. The Beardsley Bros. are working their mine at Sandy Gulch. The ore taken out by them is valued at $150 per ton. The Woodhouse, a fine piece of property, has been honded by Mr. Fields to S. F. parties. Work has been commenced. Messrs. Dennisoo and Jewel are working the Montezuma, near the Woodhouse, and are taking out good rock. George Chick is working his mioe near the Licking Fork, and is taking out rich quartz. His last crushing of ore paid him a handsome profit. Jacob Hess, whose mine is east of the Lockwood, is hard at work. The quartz takeo out by him prospects very well.

FURNACES. — Angels *Democrat*, Aug. 23: The recently finished furnaces for the chlorination works are now being put in place for use.

Del Norte.

QUARTZ.—Del Norte *Record*, Aug. 23: It is reported that Pat Casey has struck a ledge of rich quartz on Myrtle creek. In the early days that neighborhood was worked with good results.

El Dorado.

RICH GRAVEL.—*Mt. Democrat*, Aug. 23: Recently in prospectiog the Linden mine a fine body of rich gravel was struck. An upraise was in progress when unexpectedly a fine bench of gravel was struck about 10 feet above the former tunnel level. The gravel is reported as richer thao any before found in the mine. The mill was at once set to work on it with good results, and this week an increased force was put to work, the mill now pounding away night and day. Work is being pushed upon the gravel claims at Smith's Flat koown as the Toll House mine. The old shaft has been cleaned out and a prospect tunnel started showiog 18 inches of gravel. The company now having the matter in hand will run a series of drifts aod prospect shafts to determine the lowest point of bedrock, and when that is found a new incline will be made and boisting works and mill put thereon. Work is beiog shoved ahead as fast as possible, that the necessary development work can be accomplished and the buildiogs erected before the winter's raios set in. A 10-stamp mill is already on the ground ready to be put up, and the material for the necessary buildings will be on hand ready for their erection as soon as it is determined where they are to be put. The company means business, and is going at the work in a busioess-like manner.

PACIFIC.—On Saturday last Prof. Thos. Price and nephew came up from San Francisco on business pertaining to the Pacific mine, and as a result of this visit the news is promulgated that the Pacific mioe will at once start up. Orders were given to commence work and this has already been done. The shaft is to be sunk to 1200 feet before a stop is made, and how much deeper the sinking is to go is yet to be determined. But this much is assured, the Pacific mine is to be developed at once. Besides the sinking of the shaft, crosscuts and prospect tunnels will be run and the mine opened in such a way as to determioe just what there is beneath the ground. This move on the part of the owners of the Pacific is hailed with satisfaction by everybody, for it is the universal belief that there is a body of rich mineral in the Pacific, and it only needs judicious development to show it up. The surface plant of the mine is now first-class in every respect, and in thorough order for immediate work. As soon as a new wire rope for the hoisting works arrives, the work of sinking will begio. Placerville and El Dorado county are to be congratulated on the move by the Pacific. It is a mode of going to work that all have confidence in, and good results are confideotly expected.

Nevada.

SPENCEVILLE'S OUTLOOK.—Wheatland *Graphic*, Aug. 22: E. Koertner, in speaking of the mine there, says that Wohler and Pietzsch have just put in oew machinery for grinding the paint, and will use steam hereafter instead of water. They will start the machinery io operation by Monday, when they expect to turn out paint in any quaotity ready for mixing. He says that the iron mine just above Spenceville will be developed before a great while, as a stock company is being organized, with a capital of about $3,000,000. This company, if the plans are perfected, will probably build a railroad from that point to Nicolaus, to connect with the river boats, which will give that portion of the country excellent shipping facilities. Mr. Koertner says this is no mere speculation, but is bound to be a reality.

THE COE.—Grass Valley *Union*, Aug. 22: Yesterday the Coe mine commenced work with Captain Hammill in charge. The pumps were started at noon and it is the opinion of Mr. Hammill that it will take about two weeks to lower the water to the 300 level. The pump is doing its work well and no trouble with it is aoticipated.

Plumas.

A BIG DITCH PURCHASE.—Sierra *Tribune*, Aug. 23: James O'Brien of Smartsville and A. P. White of S. F. have about concluded the purchase of the Plumas Ditch and M. Co.'s property. The ditch is over 30 miles in length, and the claim, for drifting purposes, very rich. The estimated value of the old iron in the claim is sometbing over $10,000. When in repair the ditch-water for irrigating purposes alone would yield a handsome revenue. At the close of the purchase it is contemplated to repair the ditch immediately, so as to afford abundance of water to the many miners having valuable claims in the vicinity.

GENESEE VALLEY. — Greenville *Bulletin*, Aug. 2: The Genesee Valley mines are now enjoying a prosperous era. The most important of these properties is the Genesee gold mine, owned by Joseph Gruss. During the past few years Mr. Gruss has been operating the mine in a small way. However, last season he sunk a shaft to prospect and develop it, which hitherto had been worked on and near the surface only. In the past the broken-up condition of the formation in the Genesee mine led many to believe that the country of which this mine is a part was a slide from the porpbyritic range on the east. Later developments and observations show conclusively that such is not the case. The Genesee has been worked in a small way since 1858, but it now looks as if the mine were hardly prospected. In the course of time Mr. Gruss will put up heavier hoisting machinery and a better mill, and then we expect to see that property become one of the best in Plumas county. The returns are now very satisfactory. East of the Genesee and in the same formation is the Union, owned by T. E. Thurner. The vein was crossed by a tunnel run in the '50's to reach a copper ledge containiog gold. Four years ago Mr. Thurner located the property as an extension to the Genesee. The ore prospects well. It is of the same decomposed, soft nature as that found io the Genesee. Beyond the Union is the Centennial, now operated by Geo. Brandt. The ore is crushed in one of the best 10-stamp mills we have seen in the county. It is located very conveniently in reference to the mine, so that the ore can be delivered at small cost. The tailings from the mill dump into a well-equipped arastra, from which a large sbare of the gold is obtained. The Pilot, owned by J. C. Borden, situated on Cooper hill, above the Genesee mine, is said to be a good prospect, the ore being rich but the vein small. The Tutt mine is similar in character to the Green Ledge. It has small quantities of ore. The Light mines, southwest of Taylorville, are four claims owned by A. C. Light. The two farthest up the mountain, Mr. Light says, contain very large veins of quartz which will pay $5 per ton. The pocket ledge owned by him has been a noted mine. Over $30,000 has been taken out.

Placer.

THE HATHAWAY.—*Republican*, Aug. 20: The Hathaway mine in the Ophir district is one of the quartz propositions there that is proving to be a permanent, steady success. It is owned by the Valentine Bros. of S. F. The Hathaway mill with its 20 stamps is pounding away day and night without interruption, and crusbes 40 tons of quartz a day. The ore is even in value and pays $8 to $8.50 gross rigbt along, of which about $6 is in free gold and the rest is in sulphurets. Four Woodbury concentrators save about all the latter, as is shown by the fact that Gates' blanket system was tried below them, but it has been discontioued because there was not enough left to make it pay. George Taylor is superintendent.

HOGSBACK.—*Placer Herald*, Aug. 23: J. T. McCall, foreman at the Hogsback mine, was in town Monday. Mr. McCall says the new tunnel is now 2200 feet in length, leaving only 350 feet to be run to fioish it. They expect to break through ioto gravel about the first of October.

LINN.—About the first of this month fine ore was struck in the Linn mine, near Damascus, and the owners are so well satisfied that they will push the work of development uninterruptedly uotil the ledge is opened. The prospects warrant them in believing they have a permanent paying mine.

DOIG.—A. Shurtleff is running a drift from the shaft io the Doig mine. He bas run 90 feet and expects to strike in the next ten feet. If he doesn't he will run another drift in an easterly direction and connect the drifts with a crosscut. He has rock that pays $25, but is confideot that he will strike richer ore. He is right after it, and will find it if aoy one can.

San Diego.

AT JULIAN.—*San Diegan*, Aug. 18: Julian has not been so lively for years. Two months ago even there were more rooms for rent in private houses than people to occupy them, and the hotels were running at a positive loss. Now there is not an empty room in the town or vicinity. New buildings are being erected and business activity is seen in all branches of trade. The new road to Banner, four miles from Julian, is about finished. This will tap at least 50 mining properties. Teams were oever in greater demand in the district than at present, and many six-horse outfits have been taken to Julian and Banner from this city. Governor and Waldo Waterman have purchased the Gardner group of mines, and six men were put to work last week oo a contract to open up 1000 feet of tunnel. At first this is all the men that can be utilized, but as the ledges are struck more miners will be required. From a low estimate 75 men will be at work on this contract alone, as the Governor intends working every new ledge that is eocountered, and to the fullest extent. Sixty days ago there were not more than 30 miners at work io the immediate vicinity of Julian; to-day there are not less than 200 engaged. Capitalists from San Francisco have stepped in quietly and purchased the Warlock, Vulcan, Chaparral and two other mines, and are awaiting bids to let the contract for working them. Good miners can find plenty of work and sure pay on the Kentuck S., Helvetia, Ready Relief, Owens, High Peak, Stonewall, Hidden Treasure and Gold King and Queen. There is no boom in Julian, but a healthy activity is there both in mining and agriculture.

Shasta.

DOG CREEK MINES.—Cor. Redding *Democrat*, Aug. 23: We paid a visit to the McCall mine on Saturday last. There is a tunnel in 50 feet tapping the ledge at a depth of 100 feet. The ledge is four feet wide and assays from $60 to $70 per ton. The Altunis is an extension of the McCall. This ledge has a tunnel 150 feet in length tapping the main ledge at a depth of 150 feet. The ledge is three and one-half to four feet in width, and assays about the same as the McCall mine. These two mines are considered the best in the Dog Creek district. The owners of these mines, Messrs. Asa Elison, James Bard and James Hunter, are all old miners of 40 years. The Trinity mine was sold to a company from below. These people are trying to bond or buy all that is in sight.

Sierra.

EXTENSION TUNNEL. — *Mountain Messenger*, Aug. 21: The Extension tunnel is now in 4456 feet. The rock in the face is in streaks, hard and soft, as is natural in a tunnel running at right angles to the strike of the country rock—the tunnel now beading due west. There is a probability now that the tunnel bas reached the east rim of the cbannel.

ACCIDENT.—There was a premature blast in No. 4 tunnel of the Young America quartz mioe last Wednesday, and Mr. Cundy and Mr. Freitas were badly injured, and Mr. Milesi and Crossman escaped with slight bruises. Mr. Freitas' back and left leg were seriously cut, but not dangerously. Cundy died Thursday night from the effects of his injuries. The accident is reported to have occurred in this way: The night shift put off a row of boles when they quit work, and one of them did not explode. When the next sbift went to work the charge exploded. Mr. Freitas is said to be more seriously hurt than was at first supposed.

DIVINING-ROD MINING.—Sierra *Tribune*, Aug. 23: John Young, an industrious German, has run somethiog like 500 feet of tunnel in lava formation up in the vicinity of 1001 gravel mine in search of a rich quartz ledge which he has beeu told exists there by some person who locates gold something after the divining-rod style.

Siskiyou.

PLACERS.—Yreka *Journal*, Aug. 23: Mr. Deming, who recently purchased the Pinery diggings in Scott Valley, is now making arrangements to open and work them on an extensive scale by first removiog the buildings. Campbell had a good clean-up at his extensive placer mine in Quartz Valley, a few days since, realizing bigger pay than for several years past, by reason of having a greater abundance of water to work successfully. The cleanup at the Jillson & Co. blue gravel mine on Cottonwood, in this county, a few days ago, is reported to have amounted to $15,040, which is a big haul for a new mine just opened.

SALMON RIVER.—Cor. Siskiyou *Telegram*, Aug. 23: The Shumway Bros. have their head dam completed and are now at work on their ditch and flume. The Heiney claim, owned by Frank Heiney and father, commenced hoisting gravel about the middle of this week. Mr. McLauchlin closed his mine down after a long and very successful run. He picked up a piece the other day which was worth $25 and aoother that weighed $35, and several others from $10 up to an ounce. The Knownothing quartz mine is under the management of Lewis Blevins, who deserves great credit for his work. The mine looks first-rate and they are taking out coosiderable ore.

HENLEY.—Blue gravel seems to take the lead here above all other things. Jacob & Coyle's mill, which has been ruoning on gravel taken from the Black Jack mine, made a partial cleanup and $138 was taken from 47 tons of gravel. This is considered a very flattering prospect — the best ever found in Northern California. This prospect has put some of our mining men on edge, and they are busily looking around for locations. Everybody wants to be a millionaire. There are hundreds of acres of this gravel in this locality—no one can guess the exteot of it. It is capped over by sand rock. This will be a mining camp where sandstone will lie between the miner and the farmer, and both can work, one on top, the other in the bottom. The time is near at hand when the mines will go through this said stone and down to the very bowels of the earth and bring up the filthy lucre. This will prove to be one of the best mining camps on the coast. You will hear of big returns from here in the near future. Mr. Letner, who is employed at the Jillson mine, Henley, tells us that they will commence Monday to improve the mine by constructing three under-currents to catch fine gold, building 150 feet more of flume and start the drifting of a 100-foot tunnel in which they intend to fire 2500 pounds of powder to loosen things up a little. Eight men are to be employed. Mr. J. F. Calderwood of Sacramento bought 10,000 shares of Black Jack mining stock from George Bar. This is evidence that people of the lower country are pleased with our mines.

Trinity.

CANYON CREEK MINES.—*Journal*, Aug. 23: A visit last week to the mines on Canyon Creek satisfied us that this camp is destined to become one of the foremost in the county. All the ledges being worked show permanency and depth and are of good grade and size. C. C. Shattuck has made arrangements with W. J. Grigsby to put up his Huntington mill on the Buck's Ranch mine. They are now grading and getting out timbers for the purpose and it will probably be not very long before transportation of the mill will begin. They have a large ledge and where they have struck it with a tunnel it prospects well. The facilities for working this mine cannot be excelled in any country. Plenty of wood and water to run the year round. Very low-grade ore could be handled with profit. The tuonel on the Bailey is supposed to be within 10 or 20 feet of the ledge for which they are running, but as the rock is very hard through which they are running, slow progress is made, about one foot a day with two shifts being the limit. The tapping of this ledge this depth (300 feet) will make the property of great value, but even if they should not tap it, the mine is a bonanza, for the first ledge tapped is enough for a big mine. When machinery will be put on we cannot say, but it would not surprise us to see it put on at any time. The company operating on the Chloride is highly encouraged by seeing the ledge holding out as they follow it into the mountain. The ledge averages between three and four feet and the ore is of good grade. They are at work oo three tunnels and developing the property as fast as possible so that the machinery can be put on before the rainy weather sets in if the prospects justify such a move. The location of Weyand, Tighe, Everhart, and Meckle at the head of Owens creek is looking well.

LOOKING WELL.—The mine of Blakemore and Springstead near the Blakemore ranch is looking well. They are down 30 feet with the shaft and have a four-foot ledge. The ore is low-grade, but there is too much gold in it to quit work oo it.

Yuba.

MINING AND MILLING PLANT.—Grass Valley *Tidings*, Aug. 22: A meeting of the owners of the Good Hope mine at Cahbage Patch, just over the line in Yuba county, was held in this city Thursday night. It was reported that Messrs. Gamble & Guerne of Santa Rosa had remitted a check for all expenses incurred under their bond and would not resume operations. As they have not been here for several months to look at the mine, their action is inexplicable, but nevertheless satisfactory, the owners having determined to develop the property themselves. Several offers to bond have been rejected, and about the middle of next mooth the work of erecting on the property a hoisting and pumping plant and a five-stamp mill will be commenced. The shaft is down 100 feet and the ledge opened up on either side by drifts. There is ore worth $1000 on the dump.

NEVADA.

Washoe District.

ORE AND BULLION YIELD.—Virginia *Chronicle*, Aug. 23: This week's ore yield of Comstock mines aggregated 5527 tons, divided as follows: Con. Cal. & Va., 1630 tons, assay value, $23.25 per ton; Savage, 455 tons, assay value, $19.40 per ton; Yellow Jacket, 600 tons, assay value, $21; Crown Point, 784 tons, assay value, $14.71; Justice, 210 tons, assay value, $23.76; Alta, 340 toos, assay value, $21.50; Overman, 452 toos, assay value, $21; Chollar, 130 tons, assay value, $21.43; Belcher

276 ton, assay value, $21.53; Hale & Norcross, 450 tons, assay value, $20. Following was the bullion yield of the ore product from each of the above mines, estimated on the probability that 80 per cent of the value of battery sample ore pulp assays were returned: Con. Cal. & Va., $34,108; Savage, $7050; Chollar, $2228; Yellow Jacket, $10,100; Crown Point, $9250; Overman, $7600; Alta, $5850; Justice, $3850; Belcher, $3800; Hale & Norcross, $7200 Total, $92,036.

SIERRA NEVADA.—On the 630 level from the west crosscut from the southwest drift from the shaft station, 280 feet in from the mouth of the crosscut, north drift No. 2 is advanced 185 feet, continuing in porphyry and quartz of no value.

UNION CON.—On the 1465 level from the north lateral drift, opposite west crosscut No. 4, east crosscut No. 1 is advanced 722 feet, continuing in porphyry carrying clay separations.

MEXICAN.—On the 1465 level east crosscut No. 1, opposite west crosscut No. 5, is advanced 122 feet, the face in porphyry.

OPHIR.—On the 1300 level the winze is down 123 feet below the sill floor of the southwest drift on this level, and the bottom is now in porphyry. The winze will be carried down vertically to connect with the 1465 level workings, which will give good ventilation.

CON. CALIFORNIA & VIRGINIA.—The 1300 and 1500 levels continue to yield the usual quantity of ore. There has been extracted during the week from all parts of the mine 1705 tons and 1410 pounds of ore, which was shipped to the Eureka mill, battery sample assays showing an average value of $23.25 per ton [1630 tons milled]. Bullion valued at $49,798.20 shipped to the Carson Mint.

SCORPION.—The southwest drift from the 660 level continues in clay and porphyry.

ANDES.—On the 420 level a north drift from No. 1 west crosscut is out 28 feet; face in low-grade quartz.

SAVAGE.—Shipped 455 tons of ore, showing an average value of $19.40 by battery sample assays. Bullion on hand valued at $14,629.81.

HALE & NORCROSS.—Resumed ore shipments to the Nevada mill Aug. 20.

CHOLLAR.—Extracted 130 tons of ore, battery sample assays showing a value of $21.43 per ton. The falling off below the usual average is due to hanging up of stamps pending repairs to the Nevada mill.

POTOSI.—The incline winze is down 352 feet below the 930 level; bottom in porphyry and harren quartz.

ALPHA.—The 600 level southwest crosscut is in 172 feet, the face in clay and porphyry.

CON. NEW YORK.—The 650 level north drift is out 57 feet and continues in porphyry.

SILVER HILL.—The 334 level northwest drift is out 350 feet; face in clay and porphyry.

IMPERIAL.—The 1000 level west crosscut No. 1 is in 293 feet, the face in quartz and porphyry. Joint Challenge-Confidence west crosscut No. 2 is in 360 feet; face in barren quartz.

YELLOW JACKET.—Shipped 600 tons of ore showing average assay value of $21 by battery sample assays. The 500 level east crosscut No. 2, 100 feet south of No. 3, is in quartz.

CROWN POINT.—Shipped during the week 784 tons of ore, showing an average value of $14.71 per ton by pulp assays. The 300 level east stope is still showing fair grade ore which is growing narrower.

CONFIDENCE AND CHALLENGE.—The 750 level joint west crosscut No. 1 is in 40 feet; face in porphyry.

BELCHER.—Shipped during the week 276 tons of ore showing a value of $21.53 per ton by battery sample assays. Are opening second floor of 1000 level stope. A north drift from the 1300 level south drift is out eight feet, following a low-grade quartz stringer.

SEG. BELCHER.—The 850 south lateral drift is out 140 feet; face in soft porphyry. A west crosscut from the end of this drift is in 18 feet; face in soft porphyry.

JUSTICE.—During the week crushed 210 tons of ore showing a value of $23.76 per ton by battery sample assays.

ALTA.—The ore output this week was 340 tons, showing an average assay value of $21.50 per ton by pulp assays.

OVERMAN.—Shipped 396 tons of ore during the week showing an average value of $16.11 per ton by battery sample assays, of which $9 24 was gold.

OCCIDENTAL CON.—Continue to extract ore of fair quality from the stopes on the 400 and 450 levels.

Central District.

BONDED.—*Silver State*, Aug. 23: L. F. Dunn bonded the Millionaire mine in Central district, from A. H. Ruse and his son, S. W. Ruse. Some California men are about to buy the mine, and one of them, Charles Mather, is now having samples of ore taken from all parts of the mine, and will test it by working process. If the test is satisfactory, the mine will be sold.

Ely District.

INSPECTING THE BONANZA.—White Pine *News*, Aug. 21: Mrs. Josephine Walcott, in company with A. Derre (expert) and A. Waitenweil and M. Bratnober (capitalists), arrived here Monday morning from the West and spent two days examining the Joanna Bonanza. From one of the party a *News* reporter learned that the gentlemen were well pleased with what they saw in the mine and believed the property to be a valuable one. The water question—how to secure water facilities for milling purposes—seemed to be the great obstacle in the way of making the Joanna a profitable investment for capitalists. When we assured the party that that was a bugbear that need not frighten away intending purchasers, as Murray creek furnished an ample supply of water to run a thousand stamps, and it could be either purchased or leased on reasonable terms, the reply came, "the title to Murray creek is clouded with threatened litigation." This plea we consider rather flimsy, and if these parties want a good mine, and they have found what they want in the Joanna, the outside issue of water for milling purposes can be easily arranged, with not a shadow of cloud of future litigation.

ARIZONA.

GOLD.—Mohave *Miner*, Aug. 23: The gold properties in the vicinity of Cerbat Wasb are now lively. The Flores Co. is working its property with a day and night shift. Little & Maher are working a gold claim just north of Flores. Twiggs & Kelly are at work on the Robert Emmett. W. B. Campbell is working a claim across the wash from the Flores. A. James is at work on claims near the adohe cabin and has a force of men building offices and other buildings. Next week a force of men will be at work on the Esmeralda.

ASH CREEK.—Prescott *Journal Miner*, Aug. 20: Mining has received quite an impetus recently on Ash creek. A number of prospectors are at work there and are meeting with good results. Frank Kuhne, James King and John McDermid have about five tons of high-grade ore at the sampling works taken from the Sunset mine on Lynx creek. W. H. Storms, who recently took a bond on the Ohio mine in the Hassayampa district, has six men employed developing the property. He started a new crosscut on Saturday. The ore body in the mine is now about eight feet wide, and the mine is looking well. He has about 200 tons of fine gold ore on the dump.

AMULET.—F. E. Doggett, who was the discoverer of the Amulet mine on Lynx creek, and made a competence from working and selling it, after about two years spent in traveling, has again yielded to the fascination of hunting for the precious metal, and on Saturday he and his former partner in the Amulet, J. M. W. Moore, purchased a half interest in the Zero mine for $1500. This claim was owned formerly by Wm. Jennings, who, in order to get a little ready money, sold out for $200 or $300 to E. S. Clark and A. C. Gilmore, who in turn sold a small interest to C. W. Coover and others. The new owners, instead of waiting to see the ore bulge out through the top of the ground, went to work developing it, and with every stroke of the pick and every blast of giant powder the property improved in the quantity and quality of the ore.

BRITISH COLUMBIA.

THE TOUGHNUT.—Nelson *Miner*, Aug. 20: The Toughnut is looked upon as the king-pin of the claims on the western end of the Toad Mountain mineral zone. Work on the shaft was resumed about two weeks ago, and already encouraging reports are heard. The ore taken out of the shaft last summer, and also that taken from the tunnel, carries a good deal of zinc, along with galena and copper. The ore now found at the bottom of the shaft is changing to a high-grade cube galena, which, from several blowpipe assays made this week, is said to run pretty high in silver. This property is owned by men who have ample means to develop it.

GOOD ROCK FROM THE GRIZZLY.—Assessment work is being done on the Grizzly by the Frys, the original locators, they paying no attention to the parties who relocated it this spring. The Grizzly is the eastern extension of the American Flag, one of the Hall claims. The ledge is easily traceable and the ore resembles that from the great Silver King. An assay made this week from a fair average sample of the ore on the dump gave a return of $79.20 in silver.

IDAHO.

HYDRAULICKING.—Spokane Falls *Review*, Aug. 21: Capt. Sanborn of the steamer Cœur d'Alene was in the city yesterday and gave the information that operations have commenced on the placer mines located in the Cœur d'Alenes. The hydraulic piping process used was finished Tuesday and operates very successfully. Already considerable development work bas been done and a quantity of free gold extracted, showing conclusively that the district is rich with the precious metal.

NORTH STAR.—Ketchum *Keystone*, Aug. 24: The North Star has struck it rich. The operators have been following the ledge for several weeks and are down about 200 feet, where they have come upon a fine body of high-grade concentrating ore. The ledge is now about three feet wide and increasing in width as work progresses. An increased force bas been put to work on the mine. Harry Kirk, who bas been to St. Louis in the interest of the Cinnabar mine, returned last Tbursday. The machinery for a ten-stamp mill will be here in about 15 days. Titus & Griffin brought down a few tons of ore this week from the Keep Cool mine, Galena, which averaged them about $150 per ton.

RICH ORE IN GERMANIA BASIN.—Wood River *Times*, Aug. 20: Kenneth McLeod, who has just returned from a trip to Germania basin, feels quite enthusiastic over the mine properties which he saw on the way in and out. All that region will be good as soon as capital is obtained to open the mines, but in Germania basin there are 300 tons of gray copper ore, worth about $400 per ton, awaiting shipment, on the dumps of the Bibleback, Idahoan and two other claims owned by Dave Woods of Bonanza. This ore will he shipped in September.

LOWER CALIFORNIA.

ALAMO.—*Lower Californian*, Aug. 21: The Santa Clara M. Co. is working daily on the Aurora mine aod the ore is being taken out fast enough to keep the mill running night and day. The pump is at work and it enables them to work at the lower level. Work is temporarily suspended on the Encantada. Luis Lopez has a fine lot of ore from the Placer which he began crushing last Monday. It promises to run high. The Gen. Torres mine is quite a fine property. It deserves a mill instead of a single arastra. The Asbestos, the richness of which was a matter of doubt, has come in again and will prove to be O. K. after all. The Scorpion is being worked under a lease. The Tarantula is in base ore and absolutely nothing can be done with it until concentrators are introduced into some of the mills. Two placer miners took 99 pwts. and 7 grains of gold from a plat of ground 4 by 16 feet, and they have several more such plats yet to work. Placering in general is taking a boom and is getting popular. George Blethen's stamp-mill in Mexican Gulch will start up next Monday on ore from the Centipede mine. The Princesa Co. now has three big mines yielding gold, night and day. They are the Princesa, Ulises and Indio. The scene at one of these mines in the night, with their big boilers, hoists and busy men, who work in the light of many candles and lamps, shows the faith of men who dig for gold. The foundation for the concentrators to be added to the present Princesa Co. mill is complete, and the machinery that is here will be put into place. The Manzanita mill is running day and night on the Princesa Co.'s ore. Lane's mill, also, is running on their ore. The El Paso mill is not running at present, but is preparing to start up in a very short time. The El Paso Co. is building a good hoisting works on the El Paso mine, adjoining the Ulises, under the direction of Supt. McLaran.

MONTANA.

GOLD.—*Inter-Mountain*, Aug. 22: J. R. Boyce this morning was showing his friends a handsome lump of gold retort just cleaned up at the Red Lion mill, on Upper Flint creek. The cleanup is not large, but the gold is very fine. Mr. Boyce thinks the lack of success in saving a better percentage of the gold is due chiefly to their imperfect mill equipment. Their ore, he says, contains good pay and they have only to make a reasonably fair saving in order to pay good profits.

THE SOUTHERN CROSS.—The Cameron mill is pounding away steadily on Southern Cross ore, and from all indications considerably better saving of gold is being made than during the three or four months run last winter. It seems to be pretty definitely determined, however, that a high saving of Southern Cross gold cannot be made on copper plates, in the usual method of arrangements. The electro-plated coppers, however, which were added just before the mill was started up, are doing much better work than the raw copper formerly used, and it is thought probable that from 60 to 65 per cent can be saved by the use of plenty of electro-plate surface. Ultimately pans will be put in.

THE LUXEMBOURG.—Salton Cameron's new strike in the Luxembourg still lasts. He is now down about 60 feet and has had from two to four feet of ore almost from the surface—ore which all prospects well in a gold pan, and some of it is believed to be worth about $100 to the ton. Mr. Cameron's proverbial good luck seems to still stay with him.

THE M'DERMOTT.—W. F. Shanley reports that the McDermott gold mine near the head of Bear gulch is keeping up its good reputation. It is now opened to a depth of nearly 100 feet and considerable drifting has been done, showing a continuous ore body thus far about three feet wide and running between $30 and $40 per ton.

THE OBELISK.—To-day night and day shifts were put to work on the Obelisk mine near Basin City, and the tunnel which is now being run to tap the lead will he driven as fast as men can drive it.

SHIPMENT.—Boulder *Age*, Aug. 20: A recent shipment of 17½ tons of ore from the Golddust mine, Park district, to the Omaha smelter, gave a gross return of $1246, and netted the owners $886. The vein is two feet wide and very promising. A steam hoist will go up this week.

THE LEXINGTON.—*Inter-Mountain*, Aug. 22: The most energetic mining corporation in the district continues to drive its drifts and crosscuts on the 1500, and of the former it may be said with very favorable results. The mine under such able management as that of Superintendent Rueger and Foreman Kellogg will in the future be remembered as the one which determined by active and energetic experience, that deep mining was no mytb in this the richest and largest mining camp on the face of the earth to-day.

THE MOUNTAIN VIEW.—The management continues to drift on the ledges, more attention being paid to the seven, eight, nine and 1000-foot levels. All the levels below the seven are in strong leads with no breaks, being compact and mostly of a first-class character of ore.

THE ALICE is dropping its stamps on ores entirely from its own mines, and is making regular shipments of bullion. This company will, on the 1st of September, pay its 25th dividend of 6½ cents per sbare, making a total disbursement in the city of New York to the stockholders of $25,000. The mines of this company are being worked to the full capacity of their mills. This mine is second in depth only to the Lexington, and the very recent find in the Lexington on the lower levels has tended to enhance the value of this property, as the Blue Wing, whose lead is conceded to he the one encountered in the Lexington, runs for a distance of 1400 feet through the Alice ground.

UTAH.

ORE AND BULLION.—*Tidings*, Aug. 22: The week has been a good one in the production of ore, and fair for bullion. No marked event has been developed, but the advance in silver and the firmness of lead have combined to make better feeling than for a long time past. Dividend-payers can pay more than hitherto, and mines that in the past have not paid, can now be worked at a profit. The receipts of the metals in this city for the week have been to the aggregate value of $240,906, of which $149,309 was in ore and $92,507 was in bullion. The previous week the receipts were valued at $155,982 in gross, of which $87,281 was in ore and $68,161 was in bullion. The product of the Ontario for the week was of bullion, 26,625.18 fine ounces; ore sales, $23,471.18; an approximate total of $50,096.36. The Horn Silver reports no change in its average production of about 1000 to 1200 tons per month. Its ore continues to be sold in Colorado. Bullion receipts in this city for the week were valued at $35,919; base bullion, $7918; gold bar, $4000; silver ores, $9800; selected lead, $3360. The Hanauer smelter produced during the week bullion valued at $21,600. Ore receipts in this city for the week were valued at $77,808 by Wells, Fargo & Co.; $62,100 by McCornick & Co.; and $19,401 by T. R. Jones & Co.

IN TINTIC.—Salt Lake *Stock Exchange Journal*, Aug. 20: The reported great strike in the Mormon Chief, situated in the Tintic district, is now no longer a matter of conjecture. The property was experted on Wednesday of this week by J. C. Mathers, who is standard authority on mines in this locality, and by him pronounced to be as fine a piece of undeveloped property as there is to be found in the Territory. Three hand samples were tested by McVicker yesterday, with the following results: 1—137.39 ounces silver; 2—40.95 ounces silver; 3—143.75 ounces silver; all carrying a heavy trace of gold. The vein is strong and well defined, the mineral being a chloride formation, with sulpburets of silver. Pay ore is now being mined and a shipment will be made at an early date,

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING AUGUST 19, 1890.

434,552.—BEDSTEAD—F. H. B. Babbe, Santa Rosa, Cal.

434,695.—GAS ENGINE ATTACHMENT — Barrett & Daly, S. F.

434 555.—HANGING-UP ATTACHMENT FOR STAMP BATTERIES—I. K. Cleaver, Deadwood, Cal.

434 556.—FIRE-PROOF PAINT—J. T. Durkee, Port and, Or.

434434.—ANIMAL TRAP—R. E. & A. J. Eads, Pomona, Cal.

434 772.—TOOL-HANDLE—J. W. Eaton, Placerville, Cal.

434,780.—TOOL-BOX—C. O. Hescox, Tacoma, Wash.

434 712.—LIFTING JACK—Milo P. Holmes, S. F.

434,785.—GUN SIGHT—O. A. Horner, Eureka, Cal.

434,718.—LEAF-TURNER—W. F. Mitchell, S. F.

434,453.—ELEVATOR SAFETY DEVICE—E. F. Moenning, S. F.

434,565.—DRAPER SLAT PROTECTOR—Wm. D. Nelson, Traver, Cal.

434,677.—RIVETING MACHINE — Geo. Pardy, S. F.

434,463.—STEAM CONDENSER—F. Rademacher, Los Angeles, Cal.

431,814.—SUBSOIL IRRIGATOR—J. H. L. Tuck, S. F.

434,617.—STOVE-LID LIFTER — P. Wilhelm, Portland, Or.

434,494.—HARVESTER—T. C. Wilkin, Independence, Or.

434,693.—ORE CONCENTRATOR BELT—G. E. Woodbury, S. F.

The following brief list by telegraph for Aug. 26 will appear more complete on receipt of mail advices:

California—Alfred Brumwell and M. E. Doolittle, Kansas City, Mo., assignors of one-third to J. M. Thompson, S. F., cable-grip; Ellswood Chaffey, Santa Monica, mechanism for transmitting power; Frank M. Merrill, Oakland, compressed air street-car motor; Henry E. Skinner, assignor to A. T. Allen, S. F., trolling spoon. Washington—August F Baatz, Bellingham, railway brake; Frederick Ban, Tacoma, soldering iron.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

SLAT-PROTECTOR FOR DRAPERS.—Wm. M. Nelson, Traver, Tulare Co. No. 434,565. Dated Aug. 19, 1890. This invention relates to the general class of drapers or belts for agricultural implements of any nature, and it consists in the novel construction and combination of parts, the object of which is to accomplish the double purpose of protecting the ends of the draper-slats or sticks by preventing them from splitting, and of guarding the rivets which hold the sticks to the belts and preventing them from wearing loose and dropping out.

PORTABLE BEDSTEAD.—F. H. B. Babbe, Santa Rosa, Sonoma Co. No. 434,552. Dated Aug. 19, 1890. This is one of that class of bedsteads which are so constructed that their several parts may be readily taken apart, disjointed and folded upon one another, whereby the structure is reduced to small compass and may be easily disposed of or transported. The object of the invention is to provide a simple, strong and readily-manipulated bed of this class.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

CALIFORNIA SASH-BALANCE CO., S. F., Aug. 17. Object, to manufacture sash-balances. Capital stock, $250,000. Directors—A. W Forbes, Joseph D. Redding, Benjamin Marshall, Frederick R. Webster, Jerome A. Hart, Charles F. Crocker, R. P. Hurlbert.

TULARE ELECTRIC LIGHT & POWER CO., Aug. 17. Capital stock, $50,000. Directors—F. W. Eaton, John C. Turner, George A. Davis, H. C. Miller, C. D. Cushing.

BARGON COMPOUND RAIL CO., Aug. 19. Capital stock, $1,000,000. Directors—V. D. Moody, F. Chappellet, W. F. Boardman, A. P. Starr and F. K. Shattuck of Oakland, A. T. Hatch of Suisun and F. McLaughlin of Oroville.

TIME-SCHEDULE ADVERTISING & PUBLICATION CO., Aug. 18, Capital stock, $50,000. Directors—W. T. Allen, W. D. Sanborn, D. W. Hitchcock, W. H. Hurlburt and J. P. Needham.

AMERICAN INDICATOR & IMPROVEMENT CO, Aug. 20. Capital stock, $2,000,000 Directors—A. B. Spreckels, F. S Samuels, B. J. Hoffacker, T. O. Gruenhagen and M. H. Weed.

EL ALUMINA CO., Aug. 20. Object, to mine and mill certain mineral substances and ores. Capital stock, $100,000. Directors—C. P. Thore, A. A. Hoyt, C. K. Bonestell, H. S. Bridge, W. F. Gibson, W. R. Mould, L. F. Miller.

WASHINGTON COAL & LUMBER CO., Aug. 10. Location, Oregon and Washington Capital stock, $1,000,000, Directors—C. E. Eliot, W. T. Halliday, W. S. Eliot, J. D. Marsh, O. H. Hirshberger and J. L. Davie.

WARWICK M. CO., Aug. 22. Capital stock $400,000. Directors—Martin Jones, P. C. Mosebach, J. Henderson, S. Gardner, O. Woodhams.

SAN DIEGO M. CO. Capital stock, $400,000. Directors—Martin Jones, P. C. Mosebach, J. Henderson, S Gardner, O. Woodhams.

COMBINATION HAT AND PILLOW CO., Aug. 22. Object, to manufacture a peculiar kind of cap, which can be used as a pillow to sleep upon also, and in case the wearer should fall overboard the cap can be used as a life-preserver. Capital stock, $100,000. Directors—C. K. Bonnestell, P. S. Atherstone, J. C. Smith, Leon Nordman and C. H. Kimball.

DURROW WELL CO., Aug. 25. Capital stock, $200,000. Directors—G. W. Durbrow, J. Birmingham, O. E. Brady, H. Durbrow and Wm. Pierson.

UNIVERSAL ADVERTISING CO., Aug. 25. Capital stock, $500,000. Directors—C. E. Larrabee, H. F. Larrabee, Thos. F. Garber, Geo. W. Lewis, C. L. Colvin, H. A. Acker and H. G. Locher.

MECHANICAL PROGRESS.

Machinery and Hand-Power.

Hand-power was the primitive motor. It was equal to its task. The supple hand supplied the wants of man. That was enough. The product was ample and the producer busy. As population increased and civilization developed new conditions, the hand of labor was not equal to the wants of man. Invention became a necessity; machinery was industrial salvation. It supplemented elbow-grease and perspiration. Its introduction was gradual. It had its limits. The pump did not exhaust the well. The fever of getting rich was not epidemic, and patent laws were unknown. In the normal process of industrial evolution the hoot and the foot were on good terms, and it was not till number six men with number nine ambitions got on the top rail of the industrial fence that the inventive brain became a bottle of brandy and went into hysterics. Machinery was used without any regard to the displacement of labor and empty stomachs. Labor recoiled from these new conditions, and we read of riots and rebellion, and what to us today seems to be unreasonable and anarchical hostility to machine work. The masses were not to blame, in a logical sense. They saw the sky through a gimlet-hole, and measured the future by the tape line of to-day. They made a mistake, but it is understandable if we put ourselves in their wooden shoes and weigh out an ounce of bread to a pound of appetite.

Machinery, through the old eye-glasses, meant overproduction, cheap wages, rags, hunger and idleness. Such was the logic of the times, and the reason why so much of hostility pervaded the industrial world toward anything and everything that displaced the old motor of hand-power. Time has pulverized the old argument and reversed the original conditions. Invention has lifted us out of a deep hole, and machinery bridged the stream we could neither swim nor leap.

The steam engines in England alone could now do in 18 hours what it took the ancient Egyptians 20 years to accomplish with 100,000 men; and the spinning machinery in Lancashire can do in one year as much work as 21,000,000 persons in the same time could do with the old distaff and spindle. This tremendous power has been reached by degrees. It was not instantaneous but gradual, and if monopoly and the lust of money went at a gallop, the supreme power at the back of all forces put a bridle on the wild ass.

In the textile manufactures, which represent the most colossal of all modern enterprises, we get the fly-shuttle, the drop-box, the spinning-jenny, the water-frame, the power-loom, and the steam engine. Each of these inventions was opposed at its inception—it was another mouse to nibble at the poor man's cracker, and the torch and brickbat were used to intimidate the progressive manufacturer. But few men to-day have so little intelligence under their hats as not to see that with multiplied inventions have come new and increasing industries, and mechanical skill has not emptied the bag of flour, but doubled the grist at the mill. The industries of civilization increase with its inventions, and where science discovers a force in nature, its utilization is not a brake on the industrial wheel, but an additional seat in the coach and a new horse in the harness.

The electric light may dispense with the old lamp-lighter, the locomotive may halt the stage-coach, and the screw propeller may strand the old-time brigs and galleys, but the displacement of industrial methods and forces have not reduced the chances of employment, nor left the multitudes with little to eat and less to do.—*Artisan.*

How to Tin Tools.

Tools or other apparatus of iron or steel, even highly tempered steel, may be easily and cheaply coated with tin, which will give them an appearance almost equal to nickel plate and effectually prevent them from rusting. The tool should be made quite smooth and the rust, if any, removed by the use of emery paper, although this is not necessary except for the appearance. A dipping solution, consisting of tinners' soldering fluid, to which a little sal-ammoniac has been added, will be required.

An iron pot or ladle, in which the tin is to be melted, will be necessary, and must be of sufficient capacity to hold enough melted tin to cover the article.

The solution may be made by taking about five cents' worth of muriatic acid and adding to it as much sheet zinc as it will dissolve, then adding an equal bulk of water. A piece of sal-ammoniac as large as a hazel-nut should then be dissolved in the solution. When this is prepared, melt the tin and place the object in it until it becomes hot. This will not injure the temper of any steel tool, for the melting-point of tin is less than the heat required to draw the temper of any kind of steel tool. When the article has become so hot that no unmelted tin clings to it, plunge it into the solution for an instant and then into the melted tin again. In removing the article from the solution to the tin, care should be taken that the hot tin does not spatter on account of the wet article being too suddenly immersed in the melted metal. As soon as the article has attained the same temperature as the tin, it may be removed and the surplus metal wiped off with a stiff brush or any convenient material, when it will be found to be nicely and completely coated with tin, giving it an appearance nearly equal to that of a nickel plate. A hand-hammer may be neatly tinned in this manner without injury to the handle.—*The Stationary Engineer.*

THE BANDSAW FOR CUTTING METALS.—English mechanics, says the *Western Machinist*, are said to depend much upon a tool which is but little used in America, namely, a handsaw for metals. Its construction, as described, is similar to that of a heavy handsaw, with a third carrying-wheel for the saw, the object of this being to remove the up-moving side of the blade from the vicinity of the table, and thus leave a deep throat through which a large piece of work can be passed or a wide plate turned. This third wheel is placed at the back of the machine, about midway in the vertical light of the saw blade; the temper of the saw is slightly harder than that of those used for wood, and the teeth are sharpened straight across the blade by a cutter with its teeth at the right hight to suit the teeth of the saw blade. This tool is used for cutting off the spines from steel castings, the ends of bolts, to saw up steel, iron and copper plates to any form, and to rough out the jaws of eccentric rods and other forgings which would require the use of slotting machines, and it cuts as well on a circle as upon a straight line. The blade is lubricated with soap and water, and in a cut six inches long through a steel connecting-rod jaw it works freely and satisfactorily. Not infrequently circular saws of large dimensions are used for the same purpose, and, being mounted on heavy frames and fed carefully up to their work, cut off large pieces of steel, leaving nearly a smooth surface on the face of the cut.
